Wilcox, Peter Wolf, Daniel Wollschlaeger, Thomas Yee, Achim Zeileis

Maintainer Andri Signorell <andri@signorell.net>

Description A collection of basic statistic functions and convenience wrappers for efficiently describing data. The author's intention was to create a toolbox, which facilitates the (notoriously time consuming) first descriptive tasks in data analysis, consisting of calculating descriptive statistics, drawing graphical summaries and reporting the results. The package contains furthermore functions to produce documents using MS Word (or PowerPoint) and functions to import data from Excel. Many of the included functions can be found scattered in other packages and other sources written partly by Titans of R. The reason for collecting them here, was primarily to have them consolidated in ONE instead of dozens of packages (which themselves might depend on other packages which are not needed at all), and to provide a common and consistent interface as far as function and arguments naming, NA handling, recycling rules etc. are concerned. Google style guides were used as naming rules (in absence of convincing alternatives). The 'camel style' was consequently applied to functions borrowed from contributed R packages as well.

Suggests RDCOMClient, tcltk

DescTools-package	<i>Tools for Efficient Descriptive Statistics</i>
-------------------	---

Description

A collection of basic statistic functions and convenience wrappers for efficiently describing data. The author's intention was to create a toolbox, which facilitates the (notoriously time consuming) first descriptive tasks in data analysis, consisting of calculating descriptive statistics, drawing graphical summaries and reporting the results. The package contains furthermore functions to produce documents using MS Word (or PowerPoint) and functions to import data from Excel.

Many of the included functions can be found scattered in other packages and other sources written partly by Titans of R. The reason for collecting them here, was primarily to have them consolidated in ONE instead of dozens of packages (which themselves might depend on other packages which are not needed at all), and to provide a common and consistent interface as far as function and arguments naming, NA handling, recycling rules etc. are concerned. Google style guides were used as naming rules (in absence of convincing alternatives). The 'CamelStyle' was consequently applied to functions borrowed from contributed R packages as well.

Feedback, feature requests, bugreports and other suggestions are welcome! Please report problems to Stack Overflow with keyword DescTools or directly to the maintainer.
(We're approaching version 1.0, so take the opportunity...)

Details

A grouped list of the functions:

Operators, calculus, transformations:

[%\(\)%](#)

Between operators determine if a value lies within a range [a,b]

[%\)\(%](#)

Outside operators: [%\)\(%](#), [%\)\(%](#), [%\)\(%](#), [%\)\(%](#)

[%nin%](#)

"not in" operator

[%overlaps%](#)

Do two collections have common elements?

[%like%](#)

Simple operator to search for a specified pattern

[Interval](#)

Calculate the number of days of the overlapping part of two date periods

[AUC](#)

Calculate area under the curve

[Primes](#)

Find all primes less than n

Factorize	Prime factorization of integers
GCD	Calculate the greatest common divisor
LCM	Calculate the least common multiple
Permn	Determine all possible permutations of a set
Fibonacci	Generates single Fibonacci numbers or a Fibonacci sequence
Frac	Return the fractional part of a numeric value
Ndec	Count decimal places of a number
BoxCox, BoxCoxInv	Box Cox transformation and its inverse transformation
BoxCoxLambda	Return the optimal lambda for a BoxCox transformation
LogGen, LogLin	Log linear hybrid, generalized log
LogSt, LogStInv	Calculate started logarithmic transformation and it's inverse
Logit, LogitInv	Generalized logit and inverse logit function
LinScale	Simple linear scaling of a vector x
Winsorize	Data cleaning by winsorization
Trim	Trim data by omitting outlying observations
CutQ	Cut a numeric variable into quartiles
Recode	Recode a factor with altered levels
Rename	Change name(s) of a named object
Sort	Sort extension for matrices and data.frames
SortMixed, OrderMixed	Mixed sort order
DenseRank	Calculate ranks in consecutive order (no ties)
RoundM	Round to a multiple
Large, Small	Returns the kth largest, resp. smallest values
HighLow	Combines Large and Small.
Rev	Reverses the order of rows and columns of a matrix
Untable	Recreates original list based on a n-dimensional frequency table
CollapseTable	Collapse some rows/columns in a table.
Dummy	Generate dummy codes for a factor
FisherZ, FisherZInv	Fisher's z-transformation and its inverse
Midx	Calculate sequentially the midpoints of the elements of a vector
UnitConv	Return the most common unit conversions
Vigenere	Implements a Vigenere cypher, both encryption and decryption

Information and manipulation functions:

AllDuplicated	Find all values involved in ties
Closest	Return the value in a vector being closest to a given one
Coalesce	Return the first value in a vector not being NA
ZeroIfNA	Replace NAs by 0
Impute	Replace NAs by the median or another value
GetAllSubsets	Generates all possible subsets out of a list of elements
GetPairs	Generates all pairs out of one or two sets of elements
IsWhole	Is x a whole number?
IsDichotomous	Check if x contains exactly 2 values
IsOdd	Is x even or odd?
IsPrime	Is x a prime number?
IsZero	Is numeric(x) == 0, say x < machine.eps?
Label	Get or set the label attribute of an object
Mbind	Bind matrices to 3-dimensional arrays
VecRot	Shift the elements of a vector in a circular mode to the right or to the left by n characters.
Clockwise	Transform angles from counter clock into clockwise mode

split.formula
reorder.factor
LOCF

A formula interface for the base function split
Reorder the levels of a factor
Imputation of datapoints following the "last observation carried forward" rule

String functions:

StrTrim
StrTrunc

Delete white spaces from a string
Truncate string on a given length and add ellipses if it really was truncated

StrAbbr
StrCap
StrPad
StrDist
StrRev
StrCountW
StrChop
StrVal
StrPos
StrIsNumeric
FixToTab

Abbreviates a string
Capitalize the first letter of a string
Fill a string with defined characters to fit a given length
Compute Levenshtein or Hamming distance between strings
Reverse a string
Count the words in a string
Split a string by a fixed number of characters.
Extract numeric values from a string
Find position of first occurrence of a string in another one
Check whether a string does only contain numeric data
Create table out of a running text, by using columns of spaces as delimiter

Conversion functions:

AscToChar, CharToAsc
DecToBin, BinToDec
DecToHex, HexToDec
DecToOct, OctToDec
DegToRad, RadToDeg
CartToPol, PolToCart
CartToSph, SphToCart

Converts ASCII codes to characters and vice versa
Converts numbers from binmode to decimal and vice versa
Converts numbers from hexmode to decimal and vice versa
Converts numbers from octmode to decimal and vice versa
Convert degrees to radians and vice versa
Transform cartesian to polar coordinates and vice versa
Transform cartesian to spherical coordinates and vice versa

Colors:

SetAlpha
ChooseColorDlg
PlotRCol
ColorLegend
ColToGray, ColToGrey
ColToHex, HexToCol
HexToRgb
ColToHsv
ColToRgb, RgbToCol
RgbToLong
FindColor
MixColor
TextContrastColor
PalRedToBlack, PalTibco

Add transparency (alpha channel) to a color.
Display the system's color dialog to choose a color
Display R colors in a dialog
Add a color legend to a plot
Convert colors to greyscale
Convert a color into hex string

R color to HSV conversion
Color to RGB conversion and back
Convert a rgb color to a long number
Get color on a defined color range
Get the mix of two colors
Choose textcolor depending on background color
Defined color palettes

Plots:

Canvas

Canvas for geometric plotting

Mar	Set margins more comfortably.
lines.loess	Add a loess smoother and its CIs to an existing plot
lines.lm	Add the prediction of linear model and its CIs to a plot
lines.smooth.spline	Add the prediction of a smooth.spline and its CIs to a plot
ErrBars	Add horizontal or vertical error bars to an existing plot
DrawArc, DrawRegPolygon	Draw elliptic, circular arc(s) or regular polygon(s)
DrawCircle, DrawEllipse	Draw a circle, ellipse
DrawBezier	Draw a Bezier curve
DrawAnnulus, DrawAnnulusSector	Draw one or several annuli, resp. sector of an annulus
DrawBand	Draw confidence band
BoxedText	Add text surrounded by a box to a plot
Rotate	Rotate a geometric structure
SpreadOut	Spread out a vector of numbers so that there is a minimum interval between any two elements. This can be used to place textlabels in a plot so that they do not overlap.
IdentifyA	Helps identifying all the points in a specific area.
identify.formula	Formula interface for identify .
PtInPoly	Identify all the points within a polygon.
ConnLines	Calculate and insert connecting lines in a barplot
AxisBreak	Place a break mark on an axis
PlotACF, PlotMonth	Create a combined plot of a time series and its autocorrelation and partial autocorrelation
PlotArea	Create an area plot
PlotBag	Create a two-dimensional boxplot
PlotBubble	Draw a bubble plot
PlotCandlestick	Plot candlestick chart
PlotCirc	Create a circular plot
PlotCorr	Plot a correlation matrix
PlotDesc	Create a descriptive plot of a vector x dependent on its class
PlotDotCI	Plot a dotchart with confidence intervals
PlotDotCIp	Plot a dotchart with binomial confidence intervals
PlotFaces	Produce a plot of Chernoff faces
PlotFdist	Frequency distribution plot, combination of histogram, boxplot and ecdf.plot
PlotMarDens	Scatterplot with marginal densities
PlotMultiDens	Plot multiple density curves
PlotPolar	Plot values on a circular grid
PlotFun	Plot mathematical expression or a function
PolarGrid	Plot a grid in polar coordinates
PlotPyramid	Pyramid plot (back-back histogram)
PlotTreemap	Plot of a treemap.
PlotVenn	Plot a Venn diagram
PlotViolin	Plot violins instead of boxplots
PlotQQ	QQ-plot for an optional distribution
PlotWeb	Create a web plot
PlotTernary	Create a triangle or ternary plot
Distributions:	
pBenf	Benford distribution, including qBenf , dBenf , rBenf
pRevGumbel	Reverse Gumbel distribution, including qRevGumbel , dRevGumbel , rRevGumbel

qRevGumbelExp

Exponential reverse Gumbel distribution (quantile only)

 Lc
 Gini, Atkinson

Frequency table
 Two dimensional percentage table
 Return the (extended) margin tables of a table
 Calculate the expected frequencies of a nxm-table
 Mode, the most frequent value
 Geometric mean and geometric standard deviation
 Harmonic Mean
 Interface for the median of ordered factors
 Huber M-estimator of location and Tukey's biweight robust mean
 Return the Hodges-Lehmann estimator
 Return Hoeffding's D statistic
 Standard error of mean
 Confidence interval for the mean and median
 Confidence interval for the difference of two means
 Calculate a moving average
 Mean absolute deviation
 Confidence interval for the variance
 Coefficient of variation and its confidence interval
 Robust data standardization
 Robust range
 Confidence intervals for binomial and multinomial proportions
 Calculate confidence interval for a risk difference
 Calculate confidence interval for the ratio of binomial proportions.
 Confidence interval for a Poisson lambda
 Skewness and kurtosis
 Yule's Q and Yule's Y
 Tschuprow's T
 Phi, Pearson's Contingency Coefficient and Cramer's V
 Goodman Kruskal's tau-a
 Goodman Kruskal's gamma
 Kendall's tau-b
 Stuart's tau-c
 Somers' delta
 Goodman Kruskal's lambda
 Uncertainty coefficient
 Shannon's entropy, mutual information
 Rao's diversity coefficient ("quadratic entropy")
 Theil's U1 and U2 coefficient
 Combines the association measures above.
 Odds ratio and relative risk
 Cohen's Kappa, weighted Kappa and Kappa for more than 2 raters
 Cronbach's alpha
 Intraclass correlations
 Return Kripp's alpha coefficient
 Compute the Kendall coefficient of concordance
 Calculate and plot Lorenz curve
 Gini- and Atkinson coefficient

Date functions:

[day.name, day.abb](#)
[AddMonths](#)
[IsDate](#)
[IsWeekend](#)

Herfindahl- and Rosenbluth coefficient
 Compute Gini-Simpson Coefficient
 Confidence interval for Pearson's correlation coefficient
 Find the correlations for a set x of variables with set y removed
 Spearman rank correlation and its confidence intervals
 Return concordant and discordant pairs of two vectors
 Determine highly correlated variables
 Cohen's Effect Size
 Effect size calculations for ANOVAs
 Generate pairwise contrasts for using in a post-hoc test
 Stratified sampling with equal/unequal probabilities
 Outliers following Tukey's boxplot definition
 Local Outlier Factor

Signtest
 Z-test for known population variance
 Jonckheere-Terpstra test
 Page test for ordered alternatives
 Cochran's Q-test
 Siegel-Tukey test for equality in variability
 Calculate Siegel-Tukey's ranks (auxiliary function)
 Levene's test for homogeneity of variance
 Moses Test of extreme reactions
 Runs test for randomness
 Durbin-Watson test for autocorrelation
 Bartels rank test for randomness
 Jarque-Bera Test
 Anderson-Darling test for normality
 Cramer-von Mises test for normality
 Lilliefors (Kolmogorov-Smirnov) test for normality
 Pearson chi-square test for normality
 Shapiro-Francia test for normality
 Mantel-Haenszel Chisquare test
 Stuart-Maxwell marginal homogeneity test
 Lehmacher marginal homogeneity test
 Cochran-Armitage test for trend in binomial proportions
 Test for homogeneity on 2x2xk tables over strata
 Post hoc tests by Scheffe, LSD, Tukey for a aov-object
 Multiple comparisons Scheffe test
 Dunn's test of multiple comparisons
 Dunnett's test of multiple comparisons
 Hotelling's T2 test for the one and two sample case.
 Yuen's robust t-Test with trimmed means and winsorized variances

Defined names of the days
 Add a number of months to a given date
 Check whether x is a date object
 Check whether x falls on a weekend

[IsLeapYear](#)
[LastDayOfMonth](#)
[DiffDays360](#)
[Date](#)
[Day, Month, Year](#)
[Hour, Minute, Second](#)
[Week, Weekday](#)
[Quarter](#)
[YearDay, YearMonth](#)
[Now, Today](#)
[HmsToSec, SecToHms](#)
[Zodiac](#)

Check whether x is a leap year
 Return the last day of the month of the date x
 Calculate the difference of two dates using the 360-days system
 Create a date from numeric representation of year, month, day
 Extract part of a date
 Extract part of time
 Returns ISO week and weekday of a date
 Quarter of a date
 The day in the year of a date
 Get current date or date-time
 Convert h:m:s times to seconds and vice versa
 The zodiac sign of a date :-)

Finance functions:

[OPR](#)
[NPV](#)
[IRR](#)

One period returns (simple and log returns)
 Net present value
 Internal rate of return

GUI-Helpers:

[ChooseColorDlg](#)
[ImportDlg](#)
[SaveAsDlg](#)
[SelectVarDlg](#)
[PasswordDlg](#)
[PlotPar](#)

Display color dialog to choose a color
 Get path of a data file to be opened
 Save a data object by dialog
 Select elements of a set by click
 Display a dialog containing an edit field, showing only ***.
 Display the R plot parameters in a dialog

Reporting, InOut:

[WrdInsertBookmark](#)
[WrdGoto](#)
[WrdUpdateBookmark](#)
[XLGetRange](#)
[XLGetWorkbook](#)
[XLView](#)
[PpPlot](#)

Print a table with the option to have controlled linebreaks
 Easy format for numbers and dates
 Produce a rich description of an object
 Produce the same description as above but send the results to a Word document and add an adequate graphic representation
 Create a new Word, Excel or PowerPoint Instance
 Get a handle to a running Word, Excel or PowerPoint instance
 Check if the handle to a Word instance is valid or outdated
 Insert a title in Word
 Insert the active plot to Word
 Insert an R command and its output in a Word document
 Get, resp. set the font on the current cursorposition in Word
 Create a table in Word
 Insert a R-table into Word
 Insert normal text to Word
 Insert a new bookmark in a Word document
 Place cursor to a specific bookmark, or another text position.
 Update the text of a bookmark's range
 Get the values of one or several cell range(s) in Excel
 Get the values of all sheets of an Excel workbook
 Use Excel as viewer for a data.frame
 Insert active plot to PowerPoint

PpAddSlide	Adds a slide to a PowerPoint presentation
PpText	Adds a textbox with text to a PP-presentation
ParseSASDatalines	Parse a SAS "datalines" statement to read data

Tools:

PairApply	Helper for calculating functions pairwise
LsFct, LsData, LsObj	List the functions (or the data, all objects) of a package
FctArgs	Retrieve the arguments of a functions
InDots	Check if an argument is contained in ... argument and return it's value
ParseFormula	Parse a formula and return the splitted parts of if
Recycle	Recycle a list of elements to the maximal found dimension
Keywords	Get the keywords of a man page
Exec	Execute a R-command given as text
SysInfo	Get some more information about system and environment
DescToolsOptions	Get the DescTools specific options
ClipToVect	Return
Flags	Return
PlotBagPairs	Return
PlotGACF	Return
PlotHorizBar	Return
PlotMatrix	Return
Ray	Return
SampleTwins	Return

Warning

This package is still under development. Although the code seems meanwhile quite stable, until release of version 1.0 (which is expected in mid of 2015) you should be aware that everything in the package might be subject to change. Backward compatibility is not yet guaranteed. Functions may be deleted or renamed and new syntax may be inconsistent with earlier versions. By release of version 1.0 the "deprecated-defunct process" will be installed.

MS-Office

To make use of MS-Office features you must have Office in one of its variants installed. All Wrd*, XL* and Pp* functions require as well the package RDCOMClient to be installed. Hence the use of these functions is restricted to Windows systems. RDCOMClient is available at:

<http://www.stats.ox.ac.uk/pub/RWin/bin/windows/contrib/3.2/>. RDCOMClient does not exist for Mac or Linux, sorry.

AddMonths

Add a Month to a Date

Description

Simple adding a number of months to a date can lead to invalid dates, think of e.g. 2012-01-30 + 1 month. This function offers a ceiling option to make sure that the result is always a valid date, e.g. `as.Date("2013-01-31") + 1 month` will be "2013-02-28". If number `n` is negative, the months will be subtracted.

Usage

```
AddMonths(x, n, ceiling = TRUE)
```

Arguments

<code>x</code>	the date to which a number of months has to be added. <code>x</code> can be a date or an integer. If it is an integer it will be interpreted as <code>yyyymm</code> .
<code>n</code>	the number of months to be added. If <code>n</code> is negative the months will be subtracted.
<code>ceiling</code>	logic. If set to <code>TRUE</code> (default), a ceiling to the last available day of month will be set.

Value

a vector with the same dimension and type as `x`, containing the transformed dates.

Author(s)

Andri Signorell <andri@signorell.net>, based on code by Roland Rapold and Antonio

References

Date functions, like [Year](#), [Month](#), etc.

Examples

```
AddMonths(as.Date("2013-01-01"), 10)
AddMonths(as.Date("2013-01-01"), -5)

AddMonths(201301, 3)
AddMonths(201301, -5)

AddMonths(as.Date("2013-01-31"), 1)
AddMonths(as.Date("2013-01-31"), -2)

AddMonths(as.Date(c("2014-10-12", "2013-01-31", "2011-12-05")), 3)
```

Agree

Raw Simple And Extended Percentage Agreement

Description

Computes raw simple and extended percentage agreement among raters.

Usage

```
Agree(x, tolerance = 0, na.rm = FALSE)
```

Arguments

<code>x</code>	a data.frame or a $k \times m$ matrix, k subjects (in rows) m raters (in columns).
<code>tolerance</code>	number of successive rating categories that should be regarded as rater agreement (see details).
<code>na.rm</code>	logical, indicating whether NA values should be stripped before the computation proceeds. If set to TRUE only the complete cases of the ratings will be used. Defaults to FALSE.

Details

Using extended percentage agreement (`tolerance != 0`) is only possible for numerical values. If `tolerance` equals 1, for example, raters differing by one scale degree are interpreted as agreeing.

Value

numeric value of coefficient of interrater reliability

The number of finally (potentially after omitting missing values) used subjects and raters are returned as attributes:

subjects the number of subjects examined.
raters the number of raters.

AllDuplicated

Index Vector of All Values Involved in Ties

Description

The function [duplicated](#) returns a logical vector indicating which elements *x* are duplicates, but will not include the very first appearance of subsequently duplicated elements. `AllDuplicated` returns an index vector of ALL the values in *x* which are involved in ties.

So `!AllDuplicated` can be used to determine all elements of *x*, which appear exactly once (say with frequency 1).

Usage

```
AllDuplicated(x)
```

Arguments

x vector of any type.

Value

logical vector of the same dimension as *x*.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

`unique` returns a unique list of all values in `x`
`duplicated` returns an index vector flagging all elements, which appeared more than once (leaving out the first appearance!)
`union(A, B)` returns a list with the unique values from `A` and `B`
`intersect` returns all elements which appear in `A` and in `B`
`setdiff(A, B)` returns all elements appearing in `A` but not in `B`
`setequal(A, B)` returns `TRUE` if `A` contains exactly the same elements as `B`
`split(A, A)` returns a list with all the tied values in `A` (see examples)

Examples

```
x <- c(1:10, 4:6)

AllDuplicated(x)

# compare to:
duplicated(x)

x[!AllDuplicated(x)]

# union, intersect and friends...
A <- c(sort(sample(1:20, 9)), NA)
B <- c(sort(sample(3:23, 7)), NA)

# all elements from A and B (no duplicates)
union(A, B)
# all elements appearing in A and in B
intersect(A, B)
# elements in A, but not in B
setdiff(A, B)
# elements in B, but not in A
setdiff(B, A)
# Does A contain the same elements as B?
setequal(A, B)

# Find ties in a vector x
x <- sample(letters[1:10], 20, replace=TRUE)
ties <- split(x, x)

# count tied groups
sum(unlist(lapply(ties, function(x) length(x)>1))))

# length of tied groups
lapply(ties, length)[lapply(ties, length)>1]

# by means of table
tab <- table(x)
tab[tab>1]
```

```
# count elements involved in ties
sum(tab>1)
# count tied groups
sum(tab[tab>1])
```

AndersonDarlingTest *Anderson-Darling Test of Goodness-of-Fit*

Description

Performs the Anderson-Darling test of goodness-of-fit to a specified continuous univariate probability distribution.

Usage

```
AndersonDarlingTest(x, null = "punif", ..., nullname)
```

Arguments

<code>x</code>	Numeric vector of data values.
<code>null</code>	A function, or a character string giving the name of a function, to compute the cumulative distribution function for the null distribution.
<code>...</code>	Additional arguments for the cumulative distribution function.
<code>nullname</code>	Optional character string describing the null distribution. The default is "uniform distribution".

Details

This command performs the Anderson-Darling test of goodness-of-fit to the distribution specified by the argument `null`. It is assumed that the values in `x` are independent and identically distributed random values, with some cumulative distribution function F . The null hypothesis is that F is the function specified by the argument `null`, while the alternative hypothesis is that F is some other function.

Value

An object of class "htest" representing the result of the hypothesis test.

Author(s)

Original C code by George Marsaglia and John Marsaglia. R interface by Adrian Baddeley.

```

as.matrix.xtabs	<i>Xtabs to Matrix</i>
-----------------	------------------------

Description

This function turns an xtabs object into a matrix.

Usage

```
## S3 method for class 'xtabs'
as.matrix(x, ...)
```

Arguments

x	an object of class xtabs
...	additional arguments to be passed to or from methods.

Details

[xtabs](#) is indeed already a matrix, but won't be converted to a pure matrix by `as.matrix.default` function, as its classes will remain unchanged. Some functions expecting a pure matrix may fail, when fed with a xtabs object. This function will only kill the classes and the call attribute.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

```
tab <- xtabs( ~ driver + operator, data=d.pizza)

str(tab)
class(tab)

str(as.matrix(tab))
class(as.matrix(tab))
```

 AscToChar

 Converts ASCII Codes to Characters and Vice Versa

Description

AscToChar returns a character for each ASCII code (integer) supplied.

CharToAsc returns integer codes in 0:255 for each (one byte) character in strings.

Usage

```
AscToChar(i)
```

```
CharToAsc(x)
```

Arguments

i numeric (integer) vector of values in 1:255.

x [character](#) vector.

Details

Only codes in 1:127 make up the ASCII encoding which should be identical for all R versions, whereas the ‘upper’ half is often determined from the ISO-8859-1 (aka “ISO-Latin 1”) encoding, but may well differ, depending on the locale setting, see also [Sys.setlocale](#).

Note that 0 is no longer allowed since, R does not allow \0 aka nul characters in a string anymore.

Value

AscToChar and CharToAsc return a vector of the same length as their argument.

Author(s)

unknown guy out there, help text partly taken from M. Maechler’s [sfsmisc](#).

Examples

```
(x <- CharToAsc("Silvia"))
paste(AscToChar(x), collapse="")
```

 Association measures

*Cramer’s V, Pearson’s Contingency Coefficient and Phi Coefficient
Yule’s Q and Y, Tschuprow’s T*

Description

Calculate Cramer’s V, Pearson’s contingency coefficient and phi, Yule’s Q and Y and Tschuprow’s T for a table, a matrix or a data.frame.

Usage

```
Phi(x, y = NULL, ...)
ContCoef(x, y = NULL, correct = FALSE, ...)
CramerV(x, y = NULL, conf.level = NA, ...)

YuleQ(x, y = NULL, ...)
YuleY(x, y = NULL, ...)
TschuprowT(x, y = NULL, ...)
```

Arguments

<code>x</code>	can be a numeric vector, a matrix or a table.
<code>y</code>	NULL (default) or a vector with compatible dimensions to <code>x</code> . If <code>y</code> is provided, <code>table(x, y, ...)</code> is calculated.
<code>conf.level</code>	confidence level of the interval. This is only implemented for Cramer's V. If set to NA (which is the default) no confidence interval will be calculated. See examples for how to compute bootstrap intervals.
<code>correct</code>	logical. This argument only applies for <code>ContCoef</code> and indicates, whether the Sakoda's adjusted Pearson's C should be returned. Default is FALSE.
<code>...</code>	further arguments are passed to the function <code>table</code> , allowing i.e. to set <code>useNA</code> .

Details

For `x` either a matrix or two vectors `x` and `y` are expected. In latter case `table(x, y, ...)` is calculated. The function handles NAs the same way the `table` function does, so tables are by default calculated with NAs omitted.

A provided matrix is interpreted as a contingency table, which seems in the case of frequency data the natural interpretation (this is e.g. also what `chisq.test` expects).

Use the function `PairApply` (pairwise apply) if the measure should be calculated pairwise for all columns. This allows matrices of association measures to be calculated the same way `cor` does. NAs are by default omitted pairwise, which corresponds to the `pairwise.complete` option of `cor`. Use `complete.cases`, if only the complete cases of a data.frame are to be used. (see examples)

The maximum value for Phi is $\sqrt{(\min(r, c) - 1)}$, for the corrected contingency coefficient and for Cramer's V it's 1.

A Cramer's V in the range of [0, 0.3] is considered as weak, [0.3, 0.7] as medium and > 0.7 as strong. The minimum value for all is 0 under statistical independence.

Value

a single numeric value if no confidence intervals are requested,
and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

Author(s)

Andri Signorell <andri@signorell.net>,
Michael Smithson <michael.smithson@anu.edu.au> (confidence intervals for Cramer V)

v <- apply(idx, 2, function(x) CramerV(d.frm[x,1], d.frm[x,2]))
quantile(v, probs=c(0.025,0.975))

# compare this to the analytical ones
CramerV(tab, conf.level=0.95)
```

Assocs

Association Measures

Description

Collects a bunch of association measures for nominal and ordinal data.

Usage

```
Assocs(x, conf.level = 0.95)

## S3 method for class 'Assocs'
print(x, digits = 4, ...)
```

Arguments

x	a 2 dimensional contingency table or a matrix.
conf.level	confidence level of the interval. If set to NA no confidence interval will be calculated. Default is 0.95.
digits	integer which determines the number of digits used in formatting the measures of association.
...	further arguments to be passed to or from methods.

Details

This function wraps the association measures phi, contingency coefficient, Cramer's V, Goodman Kruskal's Gamma, Kendall's Tau-b, Stuart's Tau-c, Somers' Delta, Pearson and Spearman correlation, Guttman's Lambda, Theil's Uncertainty Coefficient and the mutual information.

Value

numeric matrix, dimension [1:17, 1:3]
the first column contains the estimate, the second the lower confidence interval, the third the upper one.

Atkinson

Calculate the Atkinson Index

Description

Compute the Atkinson Index. This inequality measure is useful in determining which end of the distribution contributed most to the observed inequality.

Usage

```
Atkinson(x, n = rep(1, length(x)), parameter = 0.5, na.rm = FALSE)
```

Arguments

x	a vector containing at least non-negative elements.
n	a vector of frequencies, must be same length as x.
parameter	parameter of the inequality measure (if set to NULL the default parameter of the respective measure is used).
na.rm	logical. Should missing values be removed? Defaults to FALSE.

Value

the value of the Akinson Index.

Note

This function was previously published as `ineq()` in the **ineq** package and has been integrated here without logical changes, but with some extensions for NA-handling and the use of weights.

Author(s)

Achim Zeileis <Achim.Zeileis@R-project.org>

See [Herfindahl](#), [Rosenbluth](#) for concentration measures and `ineq()` in the package **ineq** for additional inequality measures

Examples

```
# generate vector (of incomes)
x <- c(541, 1463, 2445, 3438, 4437, 5401, 6392, 8304, 11904, 22261)

# compute Atkinson coefficient with parameter=0.5
Atkinson(x, parameter=0.5)
```

AUC	<i>Area Under the Curve</i>
-----	-----------------------------

Description

Calculate the area under the curve with a naive algorithm and with a more elaborated spline approach. The curve must be given by vectors of xy-coordinates.

Usage

```
AUC(x, y, method = c("trapezoid", "step", "spline"), na.rm = FALSE)
```

Arguments

<code>x</code> , <code>y</code>	the xy-points of the curve
<code>method</code>	can be "trapezoid" (default), "step" or "spline".
<code>na.rm</code>	logical, indicating whether NA values should be stripped before the computation proceeds. In this case only the complete.cases of x and y will be used. <code>na.rm</code> defaults to FALSE.

Details

If method is set to "trapezoid" then the curve is formed by connecting all points by a direct line (composite trapezoid rule). If "step" is chosen then a stepwise connection of two points is used. For calculating the area under a spline interpolation the [splinefun](#) function is used in combination with [integrate](#).

The AUC function will handle unsorted x values (by sorting x) and ties for the x values (by ignoring duplicates).

Value

Numeric value of the area under the curve.

Author(s)

Andri Signorell <andri@signorell.net>, spline part by Claus Ekstrom <claus@rprimer.dk>

See Also

[integrate](#), [splinefun](#)

Examples

```
AUC(x=c(1,3), y=c(1,1))

AUC(x=c(1,2,3), y=c(1,2,4), method="trapezoid")
AUC(x=c(1,2,3), y=c(1,2,4), method="step")

plot(x=c(1,2,2.5), y=c(1,2,4), type="l", col="blue", ylim=c(0,4))
lines(x=c(1,2,2.5), y=c(1,2,4), type="s", col="red")

x <- seq(0, pi, length.out=200)
AUC(x=x, y=sin(x))
AUC(x=x, y=sin(x), method="spline")
```

AxisBreak

Place a Break Mark on an Axis

Description

Places a break mark on an axis on an existing plot.

Usage

```
AxisBreak(axis = 1, breakpos = NULL, pos = NA, bgcol = "white",
          breakcol = "black", style = "slash", brw = 0.02)
```

Arguments

axis	which axis to break.
breakpos	where to place the break in user units.
pos	position of the axis (see axis).
bgcol	the color of the plot background.
breakcol	the color of the "break" marker.
style	Either 'gap', 'slash' or 'zigzag'.
brw	break width relative to plot width.

Details

The 'pos' argument is not needed unless the user has specified a different position from the default for the axis to be broken.

Note

There is some controversy about the propriety of using discontinuous coordinates for plotting, and thus axis breaks. Discontinuous coordinates allow widely separated groups of values or outliers to appear without devoting too much of the plot to empty space.

The major objection seems to be that the reader will be misled by assuming continuous coordinates. The 'gap' style that clearly separates the two sections of the plot is probably best for avoiding this.

Author(s)

Jim Lemon and Ben Bolker

Examples

```
plot(3:10, main="Axis break test")

# put a break at the default axis and position
AxisBreak()
AxisBreak(2, 2.9, style="zigzag")
```

BartelsRankTest

Bartels Rank Test

Description

Performs the Bartels rank test of randomness.

Usage

```
BartelsRankTest(x, alternative, pvalue="normal")
```

Arguments

x	a numeric vector containing the observations
alternative	a character string with the alternative hypothesis. Must be one of "two.sided" (default), "left.sided" or "right.sided". You can specify just the initial letter.
pvalue	a character string specifying the method used to compute the p-value. Must be one of normal (default), beta or auto.

Details

Missing values are removed.

The RVN test statistic is

$$RVN = \frac{\sum_{i=1}^{n-1} (R_i - R_{i+1})^2}{\sum_{i=1}^n (R_i - (n+1)/2)^2}$$

where $R_i = \text{rank}(X_i), i = 1, \dots, n$. It is known that $(RVN - 2)/\sigma$ is asymptotically standard normal, where $\sigma^2 = \frac{4(n-2)(5n^2-2n-9)}{5n(n+1)(n-1)^2}$.

The possible alternative are "two.sided", "left.sided" and "right.sided". By using the alternative "left.sided" the null hypothesis of randomness is tested against a trend. By using the alternative "right.sided" the null hypothesis of randomness is tested against a systematic oscillation.

Value

A list with class "htest" containing the components:

statistic	the value of the normalized statistic test.
parameter, n	the size of the data, after the remotion of consecutive duplicate values.
p.value	the p-value of the test.
alternative	a character string describing the alternative hypothesis.
method	a character string indicating the test performed.
data.name	a character string giving the name of the data.
rvn	the value of the RVN statistic (not show on screen).
nm	the value of the NM statistic, the numerator of RVN (not show on screen).
mu	the mean value of the RVN statistic (not show on screen).
var	the variance of the RVN statistic (not show on screen).

Benford

*Benford's Distribution***Description**

Density, distribution function, quantile function, and random generation for Benford's distribution.

Usage

```
dBenf(x, ndigits = 1, log = FALSE)
pBenf(q, ndigits = 1, log.p = FALSE)
qBenf(p, ndigits = 1)
rBenf(n, ndigits = 1)
```

Arguments

<code>x, q</code>	Vector of quantiles. See <code>ndigits</code> .
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. A single positive integer. Else if <code>length(n) > 1</code> then the length is taken to be the number required.
<code>ndigits</code>	Number of leading digits, either 1 or 2. If 1 then the support of the distribution is $\{1, \dots, 9\}$, else $\{10, \dots, 99\}$.
<code>log, log.p</code>	Logical. If <code>log.p = TRUE</code> then all probabilities <code>p</code> are given as $\log(p)$.

Details

Benford's Law (aka *the significant-digit law*) is the empirical observation that in many naturally occurring tables of numerical data, the leading significant (nonzero) digit is not uniformly distributed in $\{1, 2, \dots, 9\}$. Instead, the leading significant digit ($= D$, say) obeys the law

$$P(D = d) = \log_{10} \left(1 + \frac{1}{d} \right)$$

for $d = 1, \dots, 9$. This means the probability the first significant digit is 1 is approximately 0.301, etc.

Benford's Law was apparently first discovered in 1881 by astronomer/mathematician S. Newcombe. It started by the observation that the pages of a book of logarithms were dirtiest at the beginning and progressively cleaner throughout. In 1938, a General Electric physicist called F. Benford re-discovered the law on this same observation. Over several years he collected data from different sources as different as atomic weights, baseball statistics, numerical data from *Reader's Digest*, and drainage areas of rivers.

Applications of Benford's Law has been as diverse as to the area of fraud detection in accounting and the design computers.

Value

dBenf gives the density, pBenf gives the distribution function, and qBenf gives the quantile function, and rBenf generates random deviates.

Author(s)

T. W. Yee

Source

These functions were previously published as `dbenf()` etc. in the **VGAM** package and have been integrated here without logical changes.

Between, Outside

*Operators To Check, If a Value Lies Within Or Outside a Given Range***Description**

The between and outside operators are used to check, whether a vector of given values *x* lie within a defined range (or outside respectively). The values can be numbers, text or dates. Ordered factors are supported.

Usage

```

x %()% rng
x %[]% rng
x %[]% rng
x %[]% rng

x %][% rng
x %](% rng
x %)[% rng
x %)(% rng

```

Arguments

<i>x</i>	is a variable with at least ordinal scale, usually a numeric value, but can be an ordered factor or a text as well. Texts would be treated alphabetically.
<i>rng</i>	a vector of two values or a matrix with 2 columns, defining the minimum and maximum of the range for <i>x</i> . If <i>rng</i> is a matrix, <i>x</i> or <i>rng</i> will be recycled.

Details

The between operators basically combine two conditional statements into one and simplify so the query process.

They are merely a wrapper for: *x* >= *rng*[1] & *x* <= *rng*[2], where the round bracket (means "strictly greater than >" and the square bracket [means ">=". Numerical values of *x* will be handled by C-code, which is significantly faster than two comparisons in R (especially when *x* is huge).

%][% is the negation of *%()%*, meaning all values lying outside the given range. Elements on the limits will return TRUE.

Both arguments will be recycled to the highest dimension, which is either the length of the vector or the number of rows of the matrix.

See also the routines used to check, whether two ranges overlap ([Overlap](#), [Interval](#)).

Value

A logical vector of the same length as *x*.

Author(s)

Andri Signorell <andri@signorell.net> based on C-code by Kevin Ushey <kevinushey@gmail.com>

# use it with an ordered factor and select all diamonds with
# symmetry between G (included) and X (excluded).
mean(d.diamonds[d.diamonds$symmetry %[]% c("G","X"), "price"])

# use multiple ranges
2 %[]% cbind(1:4,2:5)

# both arguments are recycled
c(2,3) %[]% cbind(1:4,2:5)
```

Description

Compute confidence intervals for binomial proportions following the most popular methods. (Wald, Wilson, Agresti-Coull, Jeffreys, Clopper-Pearson etc.)

Usage

```
BinomCI(x, n, conf.level = 0.95,
        method = c("wilson", "wald", "agresti-coull", "jeffreys",
                    "modified wilson", "modified jeffreys",
                    "clopper-pearson", "arcsine", "logit", "witting", "pratt"),
        rand = 123)
```

Arguments

x	number of successes.
n	number of trials.
conf.level	confidence level, defaults to 0.95.
method	character string specifying which method to use; this can be one out of: "wald", "wilson", "agresti-coull", "jeffreys", "modified wilson", "modified jeffreys", "clopper-pearson", "arcsine", "logit", "witting" or "pratt". Defaults to "wilson". Abbreviation of method are accepted. See details.
rand	seed for random number generator; see details.

Details

All arguments are being recycled.

The Wald interval is obtained by inverting the acceptance region of the Wald large-sample normal test.

The Wilson interval, which is the default, was introduced by Wilson (1927) and is the inversion of the CLT approximation to the family of equal tail tests of $p = p_0$. The Wilson interval is recommended by Agresti and Coull (1998) as well as by Brown et al (2001).

The Agresti-Coull interval was proposed by Agresti and Coull (1998) and is a slight modification of the Wilson interval. The Agresti-Coull intervals are never shorter than the Wilson intervals; cf. Brown et al (2001).

The Jeffreys interval is an implementation of the equal-tailed Jeffreys prior interval as given in Brown et al (2001).

The modified Wilson interval is a modification of the Wilson interval for x close to 0 or n as proposed by Brown et al (2001).

The modified Jeffreys interval is a modification of the Jeffreys interval for $x == 0 \mid x == 1$ and $x == n-1 \mid x == n$ as proposed by Brown et al (2001).

The Clopper-Pearson interval is based on quantiles of corresponding beta distributions. This is sometimes also called exact interval.

The arcsine interval is based on the variance stabilizing distribution for the binomial distribution.

The logit interval is obtained by inverting the Wald type interval for the log odds.

The Witting interval (cf. Beispiel 2.106 in Witting (1985)) uses randomization to obtain uniformly optimal lower and upper confidence bounds (cf. Satz 2.105 in Witting (1985)) for binomial proportions.

For more details we refer to Brown et al (2001) as well as Witting (1985).

Value

A vector with 3 elements for estimate, lower confidence interval and upper for the upper one.

Note

This function was previously published as `binomCI()` in the **SLmisc** package and has been integrated here with some adaptations concerning the interface, but without any change in the computation logic.

BinomRatioCI	<i>Confidence Intervals for the Ratio of Binomial and Multinomial Proportions</i>
--------------	---

Description

A number of methods have been developed for obtaining confidence intervals for the ratio of two binomial proportions. These include the Wald/Katz-log method (Katz et al. 1978), adjusted-log (Walter 1975, Pettigrew et al. 1986), Koopman asymptotic score (Koopman 1984), Inverse hyperbolic sine transformation (Newman 2001), the Bailey method (Bailey (1987), and the Noether (1957) procedure. Koopman results are found iteratively for most intervals using root finding.

Usage

```
BinomRatioCI(x1, n1, x2, n2, conf.level = 0.95, method = "katz.log",
             bonf = FALSE, tol = .Machine$double.eps^0.25, R = 1000, r = length(x1))
```

Arguments

x1	The ratio numerator number of successes. A scalar or vector.
n1	The ratio numerator number of trials. A scalar or vector of length(y1)
x2	The ratio denominator number of successes. A scalar or vector of length(y1)
n2	The ratio denominator number of trials. A scalar or vector of length(y1)
conf.level	The level of confidence, i.e. $1 - P(\text{type I error})$.
method	Confidence interval method. One of "adj.log", "bailey", "boot", "katz.log", "koopman", "sinh-1" or "noether". Partial distinct names can be used.
bonf	Logical, indicating whether or not Bonferroni corrections should be applied for simultaneous inference if y1, y2, n1 and n2 are vectors.
tol	The desired accuracy (convergence tolerance) for the iterative root finding procedure when finding Koopman intervals. The default is taken to be the smallest positive floating-point number of the workstation implementing the function, raised to the 0.25 power, and will normally be approximately 0.0001.
R	If method "boot" is chosen, the number of bootstrap iterations.
r	The number of ratios to which family-wise inferences are being made. Assumed to be length(y1).

Details

Let Y_1 and Y_2 be multinomial random variables with parameters n_1, π_{1i} , and n_2, π_{2i} , respectively; where $i = \{1, 2, 3, \dots, r\}$. This encompasses the binomial case in which $r = 1$. We define the true selection ratio for the i th resource of r total resources to be:

$$\theta_i = \frac{\pi_{1i}}{\pi_{2i}}$$

where π_{1i} and π_{2i} represent the proportional use and availability of the i th resource, respectively. Note that if $r = 1$ the selection ratio becomes relative risk. The maximum likelihood estimators for π_{1i} and π_{2i} are the sample proportions:

$$\hat{\pi}_{1i} = \frac{y_{1i}}{n_1},$$

and

$$\hat{\pi}_{2i} = \frac{y_{2i}}{n_2}$$

where y_{1i} and y_{2i} are the observed counts for use and availability for the i th resource. The estimator for θ_i is:

$$\hat{\theta}_i = \frac{\hat{\pi}_{1i}}{\hat{\pi}_{2i}}.$$

Method	Algorithm
Katz-log	$\hat{\theta}_i \times \exp(\pm z_1 - \alpha/2\hat{\sigma}_W)$, where $\hat{\sigma}_W^2 = \frac{(1-\hat{\pi}_{1i})}{\hat{\pi}_{1i}n_1} + \frac{(1-\hat{\pi}_{2i})}{\hat{\pi}_{2i}n_2}$.
Adjusted-log	$\hat{\theta}_{Ai} \times \exp(\pm z_1 - \alpha/2\hat{\sigma}_A)$, where $\hat{\theta}_{Ai} = \frac{y_{1i}+0.5/n_1+0.5}{y_{2i}+0.5/n_2+0.5}$, $\hat{\sigma}_A^2 = \frac{1}{y_1+0.5} - \frac{1}{n_1+0.5} + \frac{1}{y_2+0.5} - \frac{1}{n_2+0.5}$.
Bailey	$\hat{\theta}_i \left[\frac{1 \pm z_1 - (\alpha/2)(\hat{\pi}'_{1i}/y_{1i} + \hat{\pi}'_{2i}/y_{2i} - z_1 - (\alpha/2)^2 \hat{\pi}'_{1i} \hat{\pi}'_{2i} / 9y_{1i}y_{2i})^{1/2}/3}{1 - z_1 - (\alpha/2)^2 \hat{\pi}'_{2i} / 9y_{2i}} \right]^3$, where $\hat{\pi}'_{1i} = 1 - \hat{\pi}_{1i}$, and $\hat{\pi}'_{2i} = 1 - \hat{\pi}_{2i}$.
Inv. hyperbolic sine	$\ln(\hat{\theta}_i) \pm \left[2 \sinh^{-1} \left(\frac{z(1-\alpha/2)}{2} \sqrt{\frac{1}{y_{1i}} - \frac{1}{n_1} + \frac{1}{y_{2i}} - \frac{1}{n_2}} \right) \right]$,
Koopman	Find $X^2(\theta_0) = \chi_1^2(1 - \alpha)$, where $\tilde{\pi}_{1i} = \frac{\theta_0(n_1+y_{2i})+y_{1i}+n_2 - [\{\theta_0(n_1+y_{2i})+y_{1i}+n_2\}^2 - 4\theta_0(n_1+n_2)(y_{1i}+y_{2i})]^{0.5}}{2(n_1+n_2)}$, $\tilde{\pi}_{2i} = \frac{\tilde{\pi}_{1i}}{\theta_0}$, and $X^2(\theta_0) = \frac{(y_{1i}-n_1\tilde{\pi}_{1i})^2}{n_1\tilde{\pi}_{1i}(1-\tilde{\pi}_{1i})} \left\{ 1 + \frac{n_1(\theta_0-\tilde{\pi}_{1i})}{n_2(1-\tilde{\pi}_{1i})} \right\}$.
Noether	$\hat{\theta}_i \pm z_1 - \alpha/2\hat{\sigma}_N$, where $\hat{\sigma}_N^2 = \hat{\theta}_i^2 \left(\frac{1}{y_{1i}} - \frac{1}{n_1} + \frac{1}{y_{2i}} - \frac{1}{n_2} \right)$.

Exception handling strategies are generally necessary in the cases $y_1 = 0$, $n_1 = y_1$, $y_2 = 0$, and $n_2 = y_2$ (see Aho and Bowyer, in review).

The bootstrap method currently employs percentile confidence intervals.

Value

Returns a list of `class = "ci"`. Default output is a matrix with the point and interval estimate.

BinToDec

Converts numbers from binmode, octmode or hexmode to decimal and vice versa

Description

These functions convert numbers from one base to another. There are several solutions for this problem out there, but the naming is quite heterogeneous and so consistent function names might be helpful.

Usage

```
BinToDec(x)
DecToBin(x)
OctToDec(x)
DecToOct(x)
HexToDec(x)
DecToHex(x)
```

Arguments

x a vector of numbers, resp. alphanumerical representation of numbers (hex), to be converted.

Details

BinToDec converts numbers from binary mode into decimal values. DecToBin does it the other way round.

Oct means octal system and hex hexadecimal.

Value

A numeric or character vector of the same length as **x** containing the converted values. Binary, octal and decimal values are numeric, hex-values are returned in character mode.

```

BoxCox

Box Cox Transformation

Description

BoxCox() returns a transformation of the input variable using a Box-Cox transformation.
BoxCoxInv() reverses the transformation.

Usage

```
BoxCox(x, lambda)
BoxCoxInv(x, lambda)
```

Arguments

x	a numeric vector
lambda	transformation parameter

Details

The Box-Cox transformation is given by

$$f_{\lambda}(x) = \frac{x^{\lambda} - 1}{\lambda}$$

if $\lambda \neq 0$. For $\lambda = 0$,

$$f_0(x) = \log(x)$$

.

Value

a numeric vector of the same length as x.

Note

These two functions are borrowed from library(forecast).

bx <- BoxCox( x, lambda = BoxCoxLambda(x) )
```

BoxCoxLambda*Automatic Selection of Box Cox Transformation Parameter*

Description

An automatic selection of the Box Cox transformation parameter is estimated with two methods. Guerrero's (1993) method yields a lambda which minimizes the coefficient of variation for subseries of x . For method "loglik", the value of lambda is chosen to maximize the profile log likelihood of a linear model fitted to x . For non-seasonal data, a linear time trend is fitted while for seasonal data, a linear time trend with seasonal dummy variables is used.

Usage

```
BoxCoxLambda(x, method = c("guerrero", "loglik"), lower = -1, upper = 2)
```

Arguments

<code>x</code>	a numeric vector or time series
<code>method</code>	Choose method to be used in calculating lambda.
<code>lower</code>	Lower limit for possible lambda values.
<code>upper</code>	Upper limit for possible lambda values.

Value

a number indicating the Box-Cox transformation parameter.

Note

This function was previously published as `BoxCox.lambda()` in the **forecast** package and has been integrated here without logical changes.

          vfont = NULL, cex = 1, txt.col = NULL, font = NULL, srt = 0,
          xpad = 0.2, ypad = 0.2, density = NULL, angle = 45, col = "white",
          border = par("fg"), lty = par("lty"), lwd = par("lwd"), ...)
```

Arguments

x, y	numeric vectors of coordinates where the text labels should be written. If the length of x and y differs, the shorter one is recycled.
labels	a character vector or expression specifying the text to be written. An attempt is made to coerce other language objects (names and calls) to expressions, and vectors and other classed objects to character vectors by <code>as.character</code> . If labels is longer than x and y, the coordinates are recycled to the length of labels.
adj	The value of adj determines the way in which text strings are justified. A value of 0 produces left-justified text, 0.5 (the default) centered text and 1 right-justified text. (Any value in [0, 1] is allowed, and on most devices values outside that interval will also work.) Note that the adj argument of text also allows <code>adj = c(x, y)</code> for different adjustment in x- and y- directions.
pos	a position specifier for the text. If specified this overrides any adj value given. Values of 1, 2, 3 and 4, respectively indicate positions below, to the left of, above and to the right of the specified coordinates.
offset	when pos is specified, this value gives the offset of the label from the specified coordinate in fractions of a character width.
vfont	NULL for the current font family, or a character vector of length 2 for Hershey vector fonts. The first element of the vector selects a typeface and the second element selects a style. Ignored if labels is an expression.
cex	numeric character expansion factor; multiplied by <code>par("cex")</code> yields the final character size. NULL and NA are equivalent to 1.0.
txt.col, font	the color and (if vfont = NULL) font to be used, possibly vectors. These default to the values of the global graphical parameters in <code>par()</code> .
srt	The string rotation in degrees.
xpad, ypad	The proportion of the rectangles to the extent of the text within.
density	the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. A zero value of density means no shading lines whereas negative values (and NA) suppress shading (and so allow color filling).
angle	angle (in degrees) of the shading lines.
col	color(s) to fill or shade the rectangle(s) with. The default NA (or also NULL) means do not fill, i.e., draw transparent rectangles, unless density is specified.

<code>border</code>	color for rectangle border(s). The default is <code>par("fg")</code> . Use <code>border = NA</code> to omit borders (this is the default). If there are shading lines, <code>border = TRUE</code> means use the same colour for the border as for the shading lines.
<code>lty</code>	line type for borders and shading; defaults to "solid".
<code>lwd</code>	line width for borders and shading. Note that the use of <code>lwd = 0</code> (as in the examples) is device-dependent.
<code>...</code>	additional arguments are passed to the text function.

```

BreslowDayTest

Breslow-Day Test for Homogeneity of the Odds Ratios

Description

Calculates a Breslow-Day test of homogeneity for a $2 \times 2 \times k$ tables, to see if all strata have the same OR. If OR is not given, the Mantel-Haenszel estimate is used.

Usage

```
BreslowDayTest(x, OR = NA, correct = FALSE)
```

Arguments

<code>x</code>	a $2 \times 2 \times k$ table.
<code>OR</code>	the odds ratio to be tested against. If left undefined (default) the Mantel-Haenszel estimate will be used.
<code>correct</code>	If TRUE, the Breslow-Day test with Tarone's adjustment is computed, which subtracts an adjustment factor to make the resulting statistic asymptotically chi-square.

Details

For the Breslow-Day test to be valid, the sample size should be relatively large in each stratum, and at least 80% of the expected cell counts should be greater than 5. Note that this is a stricter sample size requirement than the requirement for the Cochran-Mantel-Haenszel test for tables, in that each stratum sample size (not just the overall sample size) must be relatively large. Even when the Breslow-Day test is valid, it might not be very powerful against certain alternatives, as discussed in Breslow and Day (1980).

```

BubbleLegend

Add a Legend to a Bubble Plot

Description

Add a legend for bubbles to a bubble plot.

Usage

```
BubbleLegend(x, y = NULL, radius, cols, labels = NULL, cols.lbl = "black",
             width = NULL, xjust = 0, yjust = 1, inset = 0, border = "black",
             frame = TRUE, adj = c(0.5, 0.5), cex = 1, bg = NULL, asp = NULL, ...)
```

Arguments

<code>x</code>	the left x-coordinate to be used to position the legend. See 'Details'.
<code>y</code>	the top y-coordinate to be used to position the legend. See 'Details'.
<code>radius</code>	the radii for the bubbles in BubbleLegend.
<code>cols</code>	the color appearing in the legend.
<code>labels</code>	a vector of labels to be placed at the right side of the legend.
<code>cols.lbl</code>	the textcolor for the labels of the bubbles.
<code>width</code>	the width of the legend.
<code>xjust</code>	how the legend is to be justified relative to the legend x location. A value of 0 means left justified, 0.5 means centered and 1 means right justified.
<code>yjust</code>	the same as <code>xjust</code> for the legend y location.
<code>inset</code>	inset distance(s) from the margins as a fraction of the plot region when legend is placed by keyword.
<code>border</code>	defines the bordor color of each rectangle. Default is none (NA).
<code>frame</code>	defines the bordor color of the frame around the whole legend. Default is none (NA).
<code>adj</code>	text alignment, horizontal and vertical.
<code>cex</code>	character extension for the labels, default 1.0.
<code>bg</code>	the background color for the bubble legend.
<code>asp</code>	the aspect ratio width/height. If this is left blank it will be calculated automatically.
<code>...</code>	further arguments are passed to the function <code>text</code> .

Details

The labels are placed in the middle of the legend.

The location of the legend may be specified by setting `x` to a single keyword from the list "bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right" and "center". This places the legend on the inside of the plot frame at the given location. Partial argument matching is used. The optional `inset` argument specifies how far the legend is inset from the plot margins. If a single value is given, it is used for both margins; if two values are given, the first is used for x-distance, the second for y-distance. This is the same behaviour as it's implemented in [legend](#).

           na.rm=TRUE, main="Price-Bubbles", panel.first=grid())

BubbleLegend("bottomleft", frame=TRUE, cols=SetAlpha("steelblue",0.5), bg="green",
             radius = c(1500, 1000, 500), labels=c(1500, 1000, 500), cex=0.8,
             cols.lbl=c("yellow", "red", "blue"))
```

Canvas

Canvas for Geometric Plotting

Description

This is just a wrapper for creating an empty plot with suitable defaults for plotting geometric shapes.

Usage

```
Canvas(xlim = NULL, ylim = xlim, xpd=par("xpd"), mar=c(5.1,5.1,5.1,5.1),
      asp = 1, bg = par("bg"), ...)
```

Arguments

<code>xlim, ylim</code>	the xlimits and ylimits for the plot. Default is <code>c(-1, 1)</code> .
<code>xpd</code>	expand drawing area, defaults to <code>par("xpd")</code> .
<code>mar</code>	set margins. Defaults to <code>c(5.1,5.1,5.1,5.1)</code> .
<code>asp</code>	numeric, giving the aspect ratio y/x. (See plot.window for details. Default is 1.
<code>bg</code>	the background color of the plot, defaults to <code>par("bg")</code> , which usually will be "white".
<code>...</code>	additional arguments are passed to the <code>plot()</code> command.

Details

The plot is created with these settings:

```
asp = 1, xaxt = "n", yaxt = "n", xlab = "", ylab = "", frame.plot = FALSE.
```

```

CartToPol

Transform Cartesian to Polar/Spherical Coordinates and vice versa

Description

Transform cartesian into polar coordinates, resp. to spherical coordinates and vice versa.

Usage

```
CartToPol(x, y)
PolToCart(r, theta)

CartToSph(x, y, z, up = TRUE)
SphToCart(r, theta, phi, up = TRUE)
```

Arguments

x, y, z	vectors with the xy-cooridanates to be transformed.
r	a vector with the radius of the points.
theta	a vector with the angle(s) of the points.
phi	a vector with the angle(s) of the points.
up	logical. If set to TRUE (default) theta is measured from x-y plane, else theta is measured from the z-axis.

Details

Angles are in radians, not degrees (i.e., a right angle is $\pi/2$). Use [DegToRad](#) to convert, if you don't wanna do it by yourself.

All parameters are recycled if necessary.

Value

PolToCart returns a list of x and y coordinates of the points.

CartToPol returns a list of r for the radius and theta for the angles of the given points.

Andri Signorell <andri@signorell.net>, Christian W. Hoffmann <christian@echoffmann.ch>

Examples

```

CartToPol(x=1, y=1)
CartToPol(x=c(1,2,3), y=c(1,1,1))
CartToPol(x=c(1,2,3), y=1)

PolToCart(r=1, theta=pi/2)
PolToCart(r=c(1,2,3), theta=pi/2)

CartToSph(x=1, y=2, z=3) # r=3.741657, theta=0.930274, phi=1.107149

```

CatTable	<i>Function to write a table</i>
----------	----------------------------------

Description

CatTable helps printing a table, if it has to be broken into multiple rows. Rowlabels will be repeated after every new break.

Usage

```
CatTable(tab, wcol, nrepchars, width = getOption("width"))
```

Arguments

tab	the rows of a table to be printed, pasted together in one string with constant columnwidth.
wcol	integer, the width of the columns. All columns must have the same width.
nrepchars	integer, the number of characters to be repeated with every break. This is typically the maximum width of the rowlabels.
width	integer, the width of the whole table. Default is the width of the current command window (getOption("width")).

CatTable(txt, nrepchars=3, wcol=5)
```

CCC

*Concordance Correlation Coefficient***Description**

Calculates Lin's concordance correlation coefficient for agreement on a continuous measure.

Usage

```
CCC(x, y, ci = "z-transform", conf.level = 0.95, na.rm = FALSE)
```

Arguments

<code>x</code>	a vector, representing the first set of measurements.
<code>y</code>	a vector, representing the second set of measurements.
<code>ci</code>	a character string, indicating the method to be used. Options are z-transform or asymptotic.
<code>conf.level</code>	magnitude of the returned confidence interval. Must be a single number between 0 and 1.
<code>na.rm</code>	logical, indicating whether NA values should be stripped before the computation proceeds. If set to TRUE only the complete cases of the ratings will be used. Defaults to FALSE.

Details

Computes Lin's (1989, 2000) concordance correlation coefficient for agreement on a continuous measure obtained by two methods. The concordance correlation coefficient combines measures of both precision and accuracy to determine how far the observed data deviate from the line of perfect concordance (that is, the line at 45 degrees on a square scatter plot). Lin's coefficient increases in value as a function of the nearness of the data's reduced major axis to the line of perfect concordance (the accuracy of the data) and of the tightness of the data about its reduced major axis (the precision of the data).

Both `x` and `y` values need to be present for a measurement pair to be included in the analysis. If either or both values are missing (i.e. coded NA) then the measurement pair is deleted before analysis.

Value

A list containing the following:

<code>rho.c</code>	the concordance correlation coefficient.
<code>s.shift</code>	the scale shift.
<code>l.shift</code>	the location shift.
<code>C.b</code>	a bias correction factor that measures how far the best-fit line deviates from a line at 45 degrees. No deviation from the 45 degree line occurs when <code>C.b = 1</code> . See Lin (1989, page 258).
<code>blalt</code>	a data frame with two columns: mean the mean of each pair of measurements, delta vector <code>y</code> minus vector <code>x</code> .

ClipToVect*Reformat a Table in the Clipboard as Vector*

Description

A table in the clipboard can not easily be inserted in the R-code. Though it can be accessed by `read.table(clipboard)`, for saving purposes it then has to be saved by `write.table`, which seems clumsy if the file has to be used by others. `ClipToVect` reformats the table in the way that it can be defined as a `data.frame` and so be pasted directly in the source code. The option will of course only be interesting for small datasets.

Usage

```
ClipToVect(doubleQuote = TRUE)
```

Arguments

`doubleQuote` logical. Defines if text should be put in doubleQuotes or singleQuotes. Default is double quotes.

Details

For using this function just copy a cell range in Excel for exmple, then run `ClipToVect` and insert the clipboard in the code file.

Value

the formatted text is copied to clipboard.

Clockwise*Calculates Begin and End Angle From a List of Given Angles in Clockwise Mode*

Description

Transforms given angles in counter clock mode into clockwise angles.

Usage

```
Clockwise(x, start = 0)
```

Arguments

`x` a vector of angles
`start` the starting angle for the transformation. Defaults to 0.

Details

Sometimes there's need for angles being defined the other way round.

Value

a data.frame with two columns, containing the start and end angles.

Closest	<i>Find the Closest Value</i>
---------	-------------------------------

Description

Find the closest value(s) of a number in a vector `x`. Multiple values will be reported, if the differences are the same.

Usage

```
Closest(x, a, which = FALSE, na.rm = FALSE)
```

Arguments

`x` the vector to be searched in
`a` the reference value
`which` a logical value defining if the index position or the value should be returned. By default will the value be returned.
`na.rm` a logical value indicating whether NA values should be stripped before the computation proceeds.

Value

the value or index in `x` which is closest to `a`

Author(s)

Andri Signorell <andri@signorell.net>

Closest(x, 6)
Closest(x, 6, which=TRUE)
```

```
Closest(c(2, 3, 4, 5), 3.5)
```

Coalesce

*Return the First Element Not Being NA***Description**

Return the first element of a vector, not being NA.

Usage

```
Coalesce(..., method = c("is.na", "is.finite"))
```

Arguments

...	the elements to be evaluated. This can either be a single vector, several vectors of same length, a matrix, a data.frame or a list of vectors (of same length). See examples.
method	one out of "is.na" (default) or "is.finite". The "is.na" option allows Inf values to be in the result, the second one eliminates them.

Details

The evaluation will be rowwise. The first element of the result is the first non NA element of the first elements of all the arguments, the second element of the result is the one of the second elements of all the arguments and so on.

Shorter inputs (of non-zero length) are NOT recycled.

The idea is borrowed from SQL. Might sometimes be useful when preparing data in R instead of in SQL.

Value

return a single vector of the first non NA element(s) of the given data structure.

Author(s)

Andri Signorell <andri@signorell.net>

)

Coalesce(d.frm)
Coalesce(as.matrix(d.frm))
Coalesce(d.frm[,2], d.frm[,3:4])
Coalesce(list(d.frm[,1], d.frm[,2]))

# returns the first finite element
Coalesce(d.frm, method="is.finite")
```

CochranArmitageTest	<i>Cochran-Armitage test for trend</i>
---------------------	--

Description

Perform a Cochran Armitage test for trend in binomial proportions across the levels of a single variable. This test is appropriate only when one variable has two levels and the other variable is ordinal. The two-level variable represents the response, and the other represents an explanatory variable with ordered levels. The null hypothesis is the hypothesis of no trend, which means that the binomial proportion is the same for all levels of the explanatory variable.

Usage

```
CochranArmitageTest(x, alternative = c("two.sided", "increasing", "decreasing"))
```

Arguments

<code>x</code>	a frequency table or a matrix.
<code>alternative</code>	a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "increasing" or "decreasing". You can specify just the initial letter.

Value

A list of class `htest`, containing the following components:

<code>statistic</code>	the z-statistic of the test.
<code>parameter</code>	the dimension of the table.

p.value the p-value for the test.
 alternative a character string describing the alternative hypothesis.
 method the character string “Cochran-Armitage test for trend”.
 data.name a character string giving the names of the data.

lungtumor <- data.frame(dose = rep(c(0, 1, 2), c(40, 50, 48)),
                        tumor = c(rep(c(0, 1), c(38, 2)),
                                rep(c(0, 1), c(43, 7)),
                                rep(c(0, 1), c(33, 15))))
tab <- table(lungtumor$dose, lungtumor$tumor)
CochranArmitageTest(tab)

# but similar to
prop.trend.test(tab[,1], apply(tab,1, sum))
```

CochranQTest

Cochran's Q test

Description

Perform the Cochran's Q test for unreplicated randomized block design experiments with a binary response variable and paired data.

Usage

```

CochranQTest(y, ...)

## Default S3 method:
CochranQTest(y, groups, blocks, ...)

## S3 method for class 'formula'
CochranQTest(formula, data, subset, na.action, ...)

```

Arguments

<code>y</code>	either a numeric vector of data values, or a data matrix.
<code>groups</code>	a vector giving the group for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one.
<code>blocks</code>	a vector giving the block for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one.
<code>formula</code>	a formula of the form <code>a ~ b c</code> , where <code>a</code> , <code>b</code> and <code>c</code> give the data values and corresponding groups and blocks, respectively.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

CochranQTest can be used for analyzing unreplicated complete block designs (i.e., there is exactly one binary observation in `y` for each combination of levels of groups and blocks) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of `y` is the same in each of the groups.

If `y` is a matrix, groups and blocks are obtained from the column and row indices, respectively. NA's are not allowed in groups or blocks; if `y` contains NA's, corresponding blocks are removed.

Note that Cochran's Q Test is analogue to the Friedman test with 0, 1 coded response. This is used here for a simple implementation.

Value

A list with class `htest` containing the following components:

<code>statistic</code>	the value of Cochran's chi-squared statistic.
<code>parameter</code>	the degrees of freedom of the approximate chi-squared distribution of the test statistic.
<code>p.value</code>	the p-value of the test.
<code>method</code>	the character string "Cochran's Q-Test".
<code>data.name</code>	a character string giving the names of the data.

# pp. S. 1824

# use expand.grid, xtabs and Untable to create the dataset
d.frm <- Untable(xtabs(c(6,2,2,6,16,4,4,6) ~ .,
  expand.grid(rep(list(c("F","U")), times=3))),
  colnames = LETTERS[1:3])

# rearrange to long shape
d.long <- reshape(d.frm, varying=1:3, times=names(d.frm)[c(1:3)],
  v.names="resp", direction="long")

# after having done the hard work of data organisation, performing the test is a piece of cake....
CochranQTest(resp ~ time | id, data=d.long)
```

CoefVar

Coefficient of Variation

Description

Calculates the coefficient of variation and its confidence limits using the noncentral t-distribution..

Usage

```
CoefVar(x, unbiased = FALSE, conf.level = NA, na.rm = FALSE)
```

Arguments

x	a (non-empty) numeric vector of data values.
unbiased	logical value determining, if a bias correction should be used (see. details). Default is FALSE.
conf.level	confidence level of the interval.
na.rm	logical. Should missing values be removed? Defaults to FALSE.

Details

In order for the coefficient of variation to be an unbiased estimate of the true population value, the coefficient of variation is corrected as:

$$CV_{corr} = CV \cdot \left(1 - \frac{1}{4 \cdot (n-1)} + \frac{1}{n} \cdot CV^2 + \frac{1}{2 \cdot (n-1)^2} \right)$$

Value

if no confidence intervals are requested: the estimate as numeric value (without any name)

else a named numeric vector with 3 elements

est	estimate
lwr.ci	lower confidence interval
upr.ci	upper confidence interval

CohenD

Cohen's Effect Size

Description

Computes the Cohen's *d* and Hedges' *g* effect size statistics.

Usage

```
CohenD(x, y = NULL, pooled = TRUE, correct = FALSE, conf.level = NA, na.rm = FALSE)
```

Arguments

<code>x</code>	a (non-empty) numeric vector of data values.
<code>y</code>	a (non-empty) numeric vector of data values.
<code>pooled</code>	logical, indicating whether compute pooled standard deviation or the whole sample standard deviation. Default is TRUE.
<code>correct</code>	logical, indicating whether to apply the Hedges correction. (Default: FALSE)
<code>conf.level</code>	confidence level of the interval. Set this to NA, if no confidence intervals should be calculated. (This is the default)
<code>na.rm</code>	logical. Should missing values be removed? Defaults to FALSE.

Value

a numeric vector with 3 elements:

<code>d</code>	the effect size d
<code>lwr.ci</code>	lower bound of the confidence interval
<code>upr.ci</code>	upper bound of the confidence interval

CohenKappa

*Cohen's Kappa and Weighted Kappa***Description**

Computes the agreement rates Cohen's kappa and weighted kappa and their confidence intervals.

Usage

```
CohenKappa(x, y = NULL, weights = c("Unweighted", "Equal-Spacing", "Fleiss-Cohen"),
           conf.level = NA, ...)
```

Arguments

<code>x</code>	can either be a numeric vector or a confusion matrix. In the latter case <code>x</code> must be a square matrix.
<code>y</code>	NULL (default) or a vector with compatible dimensions to <code>x</code> . If <code>y</code> is provided, <code>table(x, y, ...)</code> is calculated. In order to get a square matrix, <code>x</code> and <code>y</code> are coerced to factors with synchronized levels. (Note, that the vector interface can not be used together with weights.)
<code>weights</code>	either one out of "Unweighted", "Equal-Spacing", "Fleiss-Cohen", which will calculate the weights accordingly, or a user-specified matrix having the same dimensions as <code>x</code> containing the weights for each cell.
<code>conf.level</code>	confidence level of the interval. If set to NA (which is the default) no confidence intervals will be calculated.
<code>...</code>	further arguments are passed to the function <code>table</code> , allowing i.e. to set <code>useNA</code> . This refers only to the vector interface.

Details

Cohen's kappa is the diagonal sum of the (possibly weighted) relative frequencies, corrected for expected values and standardized by its maximum value.

The equal-spacing weights (see Cicchetti and Allison 1971) are defined by

$$1 - \frac{|i - j|}{r - 1}$$

`r` being the number of columns/rows, and the Fleiss-Cohen weights by

$$1 - \frac{(i - j)^2}{(r - 1)^2}$$

The latter attaches greater importance to near disagreements.

Data can be passed to the function either as matrix or data.frame in `x`, or as two numeric vectors `x` and `y`. In the latter case `table(x, y, ...)` is calculated. Thus NAs are handled the same way as `table` does. Note that tables are by default calculated **without** NAs. The specific argument `useNA` can be passed via the `...` argument.

The vector interface (`x, y`) is only supported for the calculation of unweighted kappa. For 2 factors with different levels we cannot ensure a reproducible construction of a confusion table, which is independent of the order of `x` and `y`. All weights might lead to inconsistent results. Thus the function will raise an error in such cases.

Value

if no confidence intervals are requested: the estimate as numeric value

else a named numeric vector with 3 elements

kappa	estimate
lwr.ci	lower confidence interval
upr.ci	upper confidence interval

CollapseTable

Collapse Levels of a Table

Description

Collapse (or re-label) variables in a contingency table or ftable object by re-assigning levels of the table variables.

Usage

```
CollapseTable(x, ...)
```

Arguments

x	A table or ftable object
...	A collection of one or more assignments of factors of the table to a list of levels

Details

Each of the ... arguments must be of the form `variable = levels`, where `variable` is the name of one of the table dimensions, and `levels` is a character or numeric vector of length equal to the corresponding dimension of the table.

Value

A `xtabs` and `table` objects, representing the original table with one or more of its factors collapsed or rearranged into other levels.

```

ColorLegend

Add a ColorLegend to a Plot

Description

Add a color legend, an image of a sequence of colors, to a plot.

Usage

```
ColorLegend(x, y = NULL, cols = rev(heat.colors(100)), labels = NULL,
            width = NULL, height = NULL, horiz = FALSE, xjust = 0, yjust = 1,
            inset = 0, border = NA, frame = NA, cntrlbl = FALSE,
            adj = ifelse(horiz, c(0.5, 1), c(1, 0.5)), cex = 1, ...)
```

Arguments

<code>x</code>	the left x-coordinate to be used to position the colorlegend. See 'Details'.
<code>y</code>	the top y-coordinate to be used to position the colorlegend. See 'Details'.
<code>cols</code>	the color appearing in the colorlegend.
<code>labels</code>	a vector of labels to be placed at the right side of the colorlegend.
<code>width</code>	the width of the colorlegend.
<code>height</code>	the height of the colorlegend.
<code>horiz</code>	logical indicating if the colorlegend should be horizontal; default FALSE means vertical alignment.
<code>xjust</code>	how the colorlegend is to be justified relative to the colorlegend x location. A value of 0 means left justified, 0.5 means centered and 1 means right justified.

yjust	the same as xjust for the legend y location.
inset	inset distance(s) from the margins as a fraction of the plot region when colorlegend is placed by keyword.
border	defines the border color of each rectangle. Default is none (NA).
frame	defines the border color of the frame around the whole colorlegend. Default is none (NA).
cntrlbl	defines, whether the labels should be printed in the middle of the color blocks or start at the edges of the colorlegend. Default is FALSE, which will print the extreme labels centered on the edges.
adj	text alignment, horizontal and vertical.
cex	character extension for the labels, default 1.0.
...	further arguments are passed to the function text.

Details

The labels are placed at the right side of the colorlegend and are reparted uniformly between y and y - height.

The location may also be specified by setting x to a single keyword from the list "bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right" and "center". This places the colorlegend on the inside of the plot frame at the given location. Partial argument matching is used. The optional inset argument specifies how far the colorlegend is inset from the plot margins. If a single value is given, it is used for both margins; if two values are given, the first is used for x- distance, the second for y-distance.

```

ColToGrey

*Convert Colors to Grey/Grayscale***Description**

Convert colors to grey/grayscale so that you can see how your plot will look after photocopying or printing to a non-color printer.

Usage

```

ColToGrey(col)
ColToGray(col)

```

Arguments

col	vector of any of the three kind of R colors, i.e., either a color name (an element of colors()), a hexadecimal string of the form "#rrggbb" or "#rrggbbaa" (see rgb), or an integer i meaning palette()[i]. Non-string values are coerced to integer.
-----	---

Details

Converts colors to greyscale using the formula $\text{grey} = 0.3 \cdot \text{red} + 0.59 \cdot \text{green} + 0.11 \cdot \text{blue}$. This allows you to see how your color plot will approximately look when printed on a non-color printer or photocopied.

Value

A vector of colors (greys) corresponding to the input colors.

Note

These function was previously published as Col2Grey() in the **TeachingDemos** package and has been integrated here without logical changes.

barplot(tmp, col=ColToGrey(c('red','green','blue'))))

barplot(tmp, col=c('red','#008100','#3636ff'))
barplot(tmp, col=ColToGrey(c('red','#008100','#3636ff'))))

```

ColToHex

*Convert a Color into Hex String***Description**

Convert a color given by name, by its palette index or by rgb-values into a string of the form "#rrggbb" or "#rrggbbaa".

Usage

```
ColToHex(col, alpha = 1)
```

Arguments

col	vector of any of either a color name (an element of <code>colors()</code>), or an integer <code>i</code> meaning <code>palette()[i]</code> . Non-string values are coerced to integer.
alpha	the alpha value to be used. This can be any value from 0 (fully transparent) to 1 (opaque). Default is 1.

Value

Returns the colorvalue in "#rrggbb" or "#rrggbbaa" format. (character)

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[HexToCol](#), [ColToRgb](#), [colors](#)

Examples

```

ColToHex(c("lightblue", "salmon"))

x <- ColToRgb("darkmagenta")
x[2,] <- x[2,] + 155
RgbToCol(x)

```

Description

ColToHsv transforms colors from R color into HSV space (hue/saturation/value).

Usage

```
ColToHsv(col, alpha = FALSE)
```

Arguments

col	vector of any of the three kind of R colors, i.e., either a color name (an element of <code>colors()</code>), a hexadecimal string of the form "#rrggbb" or "#rrggbbaa", or an integer <code>i</code> meaning <code>palette()[i]</code> . Non-string values are coerced to integer.
alpha	logical value indicating whether alpha channel (opacity) values should be returned.

Details

Converts a color first into RGB and from there into HSV space by means of the functions `rgb2hsv` and `col2rgb`.

Value (brightness) gives the amount of light in the color. Hue describes the dominant wavelength. Saturation is the amount of Hue mixed into the color.

An HSV colorspace is relative to an RGB colorspace, which in R is sRGB, which has an implicit gamma correction.

Value

A matrix with a column for each color. The three rows of the matrix indicate hue, saturation and value and are named "h", "s", and "v" accordingly.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

`rgb2hsv`, `ColToRgb`

Examples

```
ColToHsv("peachpuff")
ColToHsv(c(blu = "royalblue", reddish = "tomato")) # names kept
ColToHsv(1:8)
```

ColToRgb*Color to RGB Conversion*

Description

R color to RGB (red/green/blue) conversion.

Usage

```
ColToRgb(col, alpha = FALSE)
```

Arguments

col	vector of any of the three kind of R colors, i.e., either a color name (an element of <code>colors()</code>), a hexadecimal string of the form "#rrggbb" or "#rrggbbaa", or an integer <code>i</code> meaning <code>palette()[i]</code> . Non-string values are coerced to integer.
alpha	logical value indicating whether alpha channel (opacity) values should be returned.

Details

This is merely a wrapper to `col2rgb`, defined in order to follow this package's naming conventions.

Value

A matrix with a column for each color. The three rows of the matrix indicate red, green and blue value and are named "red", "green", and "blue" accordingly. The matrix might have a 4th row if an alpha channel is requested.

ColToRgb(1:8)
```

ConDisPairs

*Concordant and Discordant Pairs***Description**

This function counts concordant and discordant pairs for two variables x , y with at least ordinal scale, aggregated in a 2way table. This is the base for many association measures like Goodman Kruskal's gamma, but also all tau measures.

Usage

```
ConDisPairs(x)
```

Arguments

x a 2-dimensional table. The column and the row order must be the logical one.

Details

The code is so far implemented in R ($O(n^2)$) and therefore slow for large sample sizes (>5000). An $O(n \log(n))$ implementation is on track.

Value

a list with the number of concordant pairs, the number of discordant pairs and the matrix

Author(s)

Andri Signorell <andri@signorell.net>

plot(x, main="Confusion Matrix", ...)

## S3 method for class 'Conf'
print(x, digits = max(3, getOption("digits") - 3), ...)

Sens(x, ...)
Spec(x, ...)
```

Arguments

x	a vector, normally a factor, of predicted classes (for the default method) or an object of class table .
ref	a vector, normally a factor, of classes to be used as the reference.
pos	a character string that defines the factor level corresponding to the "positive" results.
cutoff	the cutoff point for separating the classes. This is only used if x is a glm-model and ignored else.

<code>main</code>	overall title for the plot.
<code>digits</code>	controls the number of digits to print.
<code>na.rm</code>	a logical value indicating whether or not missing values should be removed. Defaults to FALSE.
<code>...</code>	further arguments to be passed to or from methods.

Details

The functions requires that the factors have exactly the same levels.

For two class problems, the sensitivity, specificity, positive predictive value and negative predictive value is calculated using the `positive` argument. Also, the prevalence of the "event" is computed from the data (unless passed in as an argument), the detection rate (the rate of true events also predicted to be events) and the detection prevalence (the prevalence of predicted events).

Suppose a 2x2 table with notation

	Reference	
Predicted	Event	No Event
Event	A	B
No Event	C	D

The formulas used here are:

$$Sensitivity = A / (A + C)$$

$$Specificity = D / (B + D)$$

$$Prevalence = (A + C) / (A + B + C + D)$$

$$PPV = (sensitivity * Prevalence) / ((sensitivity * Prevalence) + ((1 - specificity) * (1 - Prevalence)))$$

$$NPV = (specificity * (1 - Prevalence)) / (((1 - sensitivity) * Prevalence) + (specificity * (1 - Prevalence)))$$

$$DetectionRate = A / (A + B + C + D)$$

$$DetectionPrevalence = (A + B) / (A + B + C + D)$$

See the references for discussions of the first five formulas.

For more than two classes, these results are calculated comparing each factor level to the remaining levels (i.e. a "one versus all" approach).

The overall accuracy and unweighted Kappa statistic are calculated. A p-value from McNemar's test is also computed using `mcnemar.test` (which can produce NA values with sparse tables).

The overall accuracy rate is computed along with a 95 percent confidence interval for this rate (using `BinomCI`) and a one-sided test to see if the accuracy is better than the "no information rate," which is taken to be the largest class percentage in the data.

The sensitivity is defined as the proportion of positive results out of the number of samples which were actually positive. When there are no positive results, sensitivity is not defined and a value of NA is returned. Similarly, when there are no negative results, specificity is not defined and a value of NA is returned. Similar statements are true for predictive values.

Value

a list with elements

table	the results of table on data and reference
positive	the positive result level
overall	a numeric vector with overall accuracy and Kappa statistic values
byClass	the sensitivity, specificity, positive predictive value, negative predictive value, prevalence, dection rate and detection prevalence for each class. For two class systems, this is calculated once using the positive argument

Conf(x = pred, ref = obs, pos="1")

Sens(tab) # Sensitivity
Spec(tab) # Specificity
```

 ConnLines

Add Connection Lines to a Barplot

Description

Add connection lines to a stacked barplot (beside = TRUE is not supported). The function expects exactly the same arguments, that were used to create the barplot.

Usage

```
ConnLines(..., col = 1, lwd = 1, lty = "solid", xalign = c("mar", "mid"))
```

Arguments

<code>...</code>	the arguments used to create the barplot. (The dots are sent directly to barplot).
<code>col</code>	the line color of the connection lines. Defaults to black.
<code>lwd</code>	the line width for the connection lines. Default is 1.
<code>lty</code>	the line type for the connection lines. Line types can either be specified as an integer (0=blank, 1=solid (default), 2=dashed, 3=dotted, 4=dotdash, 5=longdash, 6=twodash) or as one of the character strings "blank", "solid", "dashed", "dotted", "dotdash", "longdash", or "twodash". Default is "solid".
<code>xalign</code>	defines where the lines should be aligned to on the x-axis. Can be set either to the margins of the bars ("mar" which is the default) or to "mid". The latter will lead the connecting lines to the middle of the bars.

CorPolychor	Polychoric Correlation
Description	
Computes the polychoric correlation (and its standard error) between two ordinal variables or from their contingency table, under the assumption that the ordinal variables dissect continuous latent variables that are bivariate normal. Either the maximum-likelihood estimator or a (possibly much) quicker “two-step” approximation is available. For the ML estimator, the estimates of the thresholds and the covariance matrix of the estimates are also available.	

Usage

```
CorPolychor(x, y, ML = FALSE, control = list(), std.err = FALSE, maxcor=.9999)
```

```
## S3 method for class 'CorPolychor'
print(x, digits = max(3, getOption("digits") - 3), ...)
```

Arguments

x	a contingency table of counts or an ordered categorical variable; the latter can be numeric, logical, a factor, or an ordered factor, but if a factor, its levels should be in proper order.
y	if x is a variable, a second ordered categorical variable.
ML	if TRUE, compute the maximum-likelihood estimate; if FALSE, the default, compute a quicker “two-step” approximation.
control	optional arguments to be passed to the optim function.
std.err	if TRUE, return the estimated variance of the correlation (for the two-step estimator) or the estimated covariance matrix (for the ML estimator) of the correlation and thresholds; the default is FALSE.
maxcor	maximum absolute correlation (to insure numerical stability).
digits	integer, determining the number of digits used to format the printed result
...	not used

Value

If std.err is TRUE, returns an object of class “polycor” with the following components:

type	set to “CorPolychoric”.
rho	the CorPolychoric correlation.
row.cuts	estimated thresholds for the row variable (x), for the ML estimate.
col.cuts	estimated thresholds for the column variable (y), for the ML estimate.
var	the estimated variance of the correlation, or, for the ML estimate, the estimated covariance matrix of the correlation and thresholds.
n	the number of observations on which the correlation is based.
chisq	chi-square test for bivariate normality.
df	degrees of freedom for the test of bivariate normality.
ML	TRUE for the ML estimate, FALSE for the two-step estimate.

Otherwise, returns the CorPolychoric correlation.

Note

This is a verbatim copy from polchor function in the package polycor.

CorPolychor(x, y, ML=TRUE, std.err=TRUE) # ML estimate
```

CramerVonMisesTest	<i>Cramer-von Mises test for normality</i>
--------------------	--

Description

Performs the Cramer-von Mises test for the composite hypothesis of normality, see e.g. Thode (2002, Sec. 5.1.3).

Usage

```
CramerVonMisesTest(x)
```

Arguments

x a numeric vector of data values, the number of which must be greater than 7. Missing values are allowed.

Details

The Cramer-von Mises test is an EDF omnibus test for the composite hypothesis of normality. The test statistic is

$$W = \frac{1}{12n} + \sum_{i=1}^n \left(p_{(i)} - \frac{2i-1}{2n} \right),$$

where $p_{(i)} = \Phi([x_{(i)} - \bar{x}]/s)$. Here, Φ is the cumulative distribution function of the standard normal distribution, and \bar{x} and s are mean and standard deviation of the data values. The p-value is computed from the modified statistic $Z = W(1.0 + 0.5/n)$ according to Table 4.9 in Stephens (1986).

Value

A list with class “htest” containing the following components:

statistic	the value of the Cramer-von Mises statistic.
p.value	the p-value for the test.
method	the character string “Cramer-von Mises normality test”.
data.name	a character string giving the name(s) of the data.

```

CronbachAlpha	<i>Cronbach’s Coefficient Alpha</i>
---------------	-------------------------------------

Description

Compute Cronbach’s alpha. Cronbach’s alpha determines the internal consistency or average correlation of items in a survey instrument to gauge its reliability. This reduces to KR-20 when the columns of the data matrix are dichotomous.

Usage

```
CronbachAlpha(x, conf.level = NA, cond = FALSE, na.rm = FALSE)
```

Arguments

x	$n \times m$ matrix or dataframe with item responses, k subjects (in rows) m items (in columns).
conf.level	confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
cond	logical. If set to TRUE, alpha is additionally calculated for the dataset with each item left out.

na.rm logical, indicating whether NA values should be stripped before the computation proceeds. If set to TRUE only the complete cases of the ratings will be used. Defaults to FALSE.

Value

Either a numeric value or
a named vector of 3 columns if confidence levels are required (estimate, lower and upper ci) or

a list containing the following components, if the argument cond is set to TRUE:

unconditional Cronbach's Alpha, either the single value only or with confidence intervals

condCronbachAlpha

The alpha that would be realized if the item were excluded

## End(Not run)
```

CutQ

Create a Factor Variable Using the Quantiles of a Continuous Variable

Description

Create a factor variable using the quantiles of a continuous variable.

Usage

```
CutQ(x, breaks = quantile(x, seq(0, 1, by = 0.25), na.rm = TRUE),  
     labels = NULL, na.rm = FALSE, ...)
```

Arguments

x	continuous variable.
breaks	the breaks for creating groups. By default the quantiles will be used, say <code>quantile(seq(0, 1, by = 0.25))</code> quantiles. See quantile for details.
labels	labels for the levels of the resulting category. By default, labels are defined as Q1, Q2 to the length of breaks - 1. The parameter is passed to cut , so if labels are set to FALSE, simple integer codes are returned instead of a factor.
na.rm	Boolean indicating whether missing values should be removed when computing quantiles. Defaults to TRUE.
...	Optional arguments passed to cut .

Details

This function uses [quantile](#) to obtain the specified quantiles of x, then calls [cut](#) to create a factor variable using the intervals specified by these quantiles.

It properly handles cases where more than one quantile obtains the same value, as in the second example below. Note that in this case, there will be fewer generated factor levels than the specified number of quantile intervals.

Value

Factor variable with one level for each quantile interval given by q.

d.countries

ISO 3166-1 Country Codes

Description

Country codes published by the International Organization for Standardization (ISO) define codes for the names of countries, dependent territories, and special areas of geographical interest.

Usage

```
data("d.countries")
```

Format

A data frame with 249 observations on the following 4 variables.

name a character vector, the name of the country.

a2 a character vector, two-letter country codes (aka alpha-2) which are the most widely used of the three, and used most prominently for the Internet's country code top-level domains (with a few exceptions).

a3 a character vector, three-letter country codes (aka alpha-3) which allow a better visual association between the codes and the country names than the alpha-2 codes.

code a numeric vector, three-digit country codes which are identical to those developed and maintained by the United Nations Statistics Division, with the advantage of script (writing system) independence, and hence useful for people or systems using non-Latin scripts.

region the region of the country

pop2012 the population in 2012

gpci2012 the gross national income (per capita) in dollars per country in 2012.

d.periodic

*Periodic Table of Elements***Description**

This data.frame contains the most important properties of the periodic table of the elements.

Usage

```
data(d.periodic)
```

Format

A data frame with 110 observations on the following 24 variables.

symbol symbol of an element.

nr atomic number of an atomic symbol.

name name of an element.

group group of an element. Possible results are: Alkali Earth, Alkali Met., Halogen, Metal, Noble Gas, Non-Metal, Rare Earth and Trans. Met.

weight atomic weight of an element. The values are based upon carbon-12. () indicates the most stable or best known isotope.

meltpt melting point of an element in [K].

boilpt boiling point of an element in Kelvin [K].

dens density of an element in [g/cm3] at 300K and 1 atm.

elconf electron configuration of an element.

oxstat oxidation states of an element. The most stable is indicated by a "!".

struct crystal structure of an element. Possible results are: Cubic, Cubic body centered, Cubic face centered, Hexagonal, Monoclinic, Orthorhombic, Rhombohedral, Tetragonal

covrad covalent radius of an element in Angstroem [A].

arad atomic radius of an element in Angstroem.

avol atomic volume of an element in [cm3/mol].

speat specific heat of an element in [J/(g K)].

eneg electronegativity (Pauling's) of an element.

fusheat heat of fusion of an element in [kJ/mol].

vapheat heat of vaporization of an element in [kJ/mol].

elcond electrical conductivity of an element in [1/(Ohm cm)].

thermcond thermal conductivity of an element in [W/(cm K)].

ionpot1 first ionization potential of an element in [V].

ionpot2 second ionization potential of an element in [V].

ionpot3 third ionization potential of an element in [V].

discyear year of discovery of the element

d.pizza

*Data pizza***Description**

An artificial dataset inspired by a similar dataset `pizza.sav` in *Arbeitsbuch zur deskriptiven und induktiven Statistik* by Toutenburg et.al.

The dataset contains data of a pizza delivery service in London, delivering pizzas to three areas. Every record defines one order/delivery and the according properties. A pizza is supposed to taste good, if it's temperature is high enough, say 45 Celsius. So it might be interesting for the pizza delivery service to minimize the delivery time.

The dataset is designed to be possibly evil. It contains the most used datatypes as numerics, factors, ordered factors, integers, logicals and a date. NAs are scattered everywhere, besides in the index.

Usage

```
data(d.pizza)
```

Format

A data frame with 1209 observations on the following 17 variables.

`index` a numeric vector, indexing the records (no missings here).

`date` Date, the delivery date

`week` integer, the weeknumber

`weekday` integer, the weekday

`area` factor, the three London districts: Brent, Camden, Westminster

`count` integer, the number of pizzas delivered

`rabate` logical, TRUE if a rabate has been given

`price` numeric, the total price of delivered pizza(s)

`operator` a factor with levels Allanah Maria Rhonda

`driver` a factor with levels Carpenter Carter Taylor Butcher Hunter Miller Farmer

`delivery_min` numeric, the delivery time in minutes (decimal)

`temperature` numeric, the temperature of the pizza in degrees Celsius when delivered to the customer

`wine_ordered` integer, 1 if wine was ordered, 0 if not

`wine_delivered` integer, 1 if wine was delivered, 0 if not

`wrongpizza` logical, TRUE if a wrong pizza was delivered

`quality` ordered factor with levels low < medium < high, defining the quality of the pizza when delivered

Details

The dataset contains NAs randomly scattered.

Date

Create a Date from Numeric Representation

Description

Create a date out of either year, month and day supplied by single values or out of one single numeric value in the form `yyyymmdd`.

Usage

```
Date(year, month = NA, day = NA)
```

Arguments

`year`, `month`, `day`
numerical values to specify a day. If month and day are omitted the function tries to interpret year as yearmonthday (`yyyymmdd`) long integer value.

Details

All arguments are recycled if necessary.

The function is a convenience wrapper for `ISOdate`, which yields a datetime object, which again is an overkill, if only dates are needed.

Value

a vector with the same length as the input vector of class "Date".

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[ISOdate](#)

Examples

```
Date(2011, 3, 1:15)

Date(20120305:20120315)
```

Description

Some more date functions for making daily life a bit easier. The first ones extract a specific part of a given date, others check some conditions.

Usage

```

Year(x)
Quarter(x)
Month(x, fmt = c("m", "mm", "mmm"), lang = c("local", "engl"),
      stringsAsFactors = TRUE)
Week(x, method = c("iso", "us"))
Day(x)
Weekday(x, fmt = c("d", "dd", "ddd"), lang = c("local", "engl"),
        stringsAsFactors = TRUE)
YearDay(x)
YearMonth(x)

Day(x) <- value

IsWeekend(x)
IsLeapYear(x)

Hour(x)
Minute(x)
Second(x)

Now()
Today()

DiffDays360(start_d, end_d, method = c("eu", "us"))
LastDayOfMonth(x)

```

Arguments

<code>x</code>	the date to be evaluated.
<code>fmt</code>	format string, defines how the month or the weekday are to be formatted. Defaults to "m", resp. "d". Is ignored for other functions.
<code>value</code>	new value
<code>lang</code>	the language for the months and daynames. This can be either the current locale (default) or english.
<code>stringsAsFactors</code>	logical. Defines if the result should be coerced to a factor, using the local definitions as levels. The result would be an ordered factor. Default is TRUE.
<code>start_d, end_d</code>	the start, resp. end date for <code>DiffDays360</code> .

method one out of "eu", "us", setting either European or US-Method calculation mode. Default is "eu".

Details

These functions are mainly convenience wrappers for the painful `format()` and its strange codes... Based on the requested time component, the output is as follows:

Year returns the year of the input date in yyyy format.

Quarter returns the quarter of the year (1 to 4) for the input date.

Month returns the month of the year (1 to 12) for the input date.

Week returns the week of the year for the input date (0 to 53), as defined in ISO8601.

Weekday returns the week day of the input date. (1 - Monday, 2 - Tuesday, ... 7 - Sunday). (Names and abbreviations are either english or in the current locale!)

YearDay returns the day of the year numbering (1 to 366).

Day returns the day of the month (1 to 31).

YearMonth returns the yearmonth representation (yyyymm) of a date as long integer.

Hour, Minute, Second return the hour, minute resp. second from a `Posixlt` object.

Today, Now return the current date, resp. the current date and time.

IsWeekend returns TRUE, if the date x falls on a weekend.

IsLeapYear returns TRUE, if the year of the date x is a leap year.

The day can not only be extracted, but as well be defined. See examples.

DiffDays360 calculates the difference between 2 dates using the 360-days convention.

LastDayOfMonth returns the last day of the month of the given date(s).

Value

a vector of the same dimension as x, consisting of either numeric values or characters depending on the function used.

```

day.name

Build-in Constants Extension

Description

There's a small number of built-in constants in R. We have month.name and month.abb but nothing similar for days. Here it is.

Usage

```

day.name
day.abb

```

See Also

[month.name](#), [month.abb](#)

DegToRad

Convert Degrees to Radians and vice versa

Description

Convert degrees to radians (and back again).

Usage

```

DegToRad(deg)
RadToDeg(rad)

```

Arguments

deg a vector of angles in degrees.
rad a vector of angles in radians.

Value

DegToRad returns a vector of the same length as deg with the angles in radians.
RadToDeg returns a vector of the same length as rad with the angles in degrees.

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
DegToRad(c(90,180,270))  

RadToDeg( c(0.5,1,2) * pi)
```

DenseRank	<i>Dense Ranks</i>
-----------	--------------------

Description

Returns the dense ranks of the values in a vector. DenseRank gives the ranking within the vector x, but the ranks are consecutive. No ranks are skipped if there are ranks with multiple items. (Unlike [rank](#) gives the ranking within the vector x too, but ties are assigned the same rank, with the next ranking(s) skipped.)

Usage

```
DenseRank(x, na.last = TRUE)
```

Arguments

x a numeric, complex, character or logical vector.
na.last for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed; if "keep" they are kept with rank NA.

Value

A numeric vector of the same length as x with names copied from x (unless na.last = NA, when missing values are removed). The vector is of integer type unless x is a long vector.

Author(s)

Andri Signorell <andri@signorell.net>

[rank](#), [factor](#), [order](#), [sort](#)

Examples

```
(r1 <- rank(x1 <- c(3, 1, 4, 15, 92)))

x2 <- c(3, 1, 4, 1, 5, 9, 2, 6, 5, 3, 5)
names(x2) <- letters[1:11]
(r2 <- rank(x2))      # ties are averaged
(r2 <- DenseRank(x2)) # ranks are enumerated
```

Desc	<i>Describe Data</i>
------	----------------------

Description

Produce summaries of various types of variables. Calculate descriptive statistics for `x` and use `Word` as reporting tool for the numeric results and for descriptive plots. The appropriate statistics are chosen depending on the class of `x`. The general intention is to simplify the description process for lazy typers and return a quick, but rich summary.

Usage

```
Desc(x, ..., wrd = NULL)
## Default S3 method:
Desc(x, ...)
```

Arguments

<code>x</code>	the object to be described.
<code>wrd</code>	a pointer to a running <code>Word</code> instance. If this is <code>NULL</code> then output will be directed to console, else to <code>Word</code> .
<code>...</code>	the dots are passed to the specific function.

Details

`Desc` is a generic function. It dispatches to one of the methods above depending on the class of its first argument. Typing `?Desc + TAB` at the prompt should present a choice of links: the help pages for each of these `Desc` methods (at least if you're using `RStudio`, which anyway is recommended). You don't need to use the full name of the method although you may if you wish; i.e., `Desc(x)` is idiomatic R but you can bypass method dispatch by going direct if you wish: `Desc.numeric(x)`. More details about the results of the methods can be found in the type-specific help texts.

Value

partly results are returned

Author(s)

Andri Signorell

DescNumNum(x=d.pizza$delivery_min, y=d.pizza$price)
```

Desc.data.frame	<i>Describe a data.frame Or a List</i>
-----------------	--

Description

Describes all the columns of a data.frame, resp. all the elements of a list, according to their class.

Usage

```
## S3 method for class 'data.frame'
Desc(x, sep = paste(rep("-", (as.numeric(options("width")) - 2)), collapse = ""),
     main = NULL, enum = TRUE, ...)

## S3 method for class 'list'
Desc(x, sep = paste(rep("-", (as.numeric(options("width")) - 2)), collapse = ""),
     main = NULL, enum = TRUE, ...)
```

Arguments

x	the data.frame, the matrix or the list to be described
sep	character. The separator for the title.
main	a vector with the main titles for the description of the variables. If this is left blank, the title will be composed as: number - variablename (class(es)).
enum	logical, determining if the number should be included or not. Default is TRUE. The numbers may be redundant or inconsistent, if a Word report with enumerated headings is created.
...	the dots are passed to the child functions.

Details

See detailed information in the description of the according object interfaces.

Value

No results are returned.

Desc(as.list(d.pizza[,c("temperature", "count", "driver", "date", "wine_delivered")])) )
```

Desc.Date

Describe a Date Vector

Description

Description interface for dates. We do here what seems reasonable for describing dates. We start with a short summary about length, number of NAs and extreme values, before we describe the frequencies of the weekdays and months, rounded up by a chi-square test.

Usage

```
## S3 method for class 'Date'
Desc(x, main = NULL, maxrows = 10, digits = 3, dprobs = NULL, mprobs = NULL,
      plotit = getOption("plotit", FALSE), ...)
```

Arguments

x	the Date vector to be described.
main	the caption of the output.
maxrows	numeric. Defines the maximum number of rows to be reported. Default is 10 (most frequent ones). If maxrows < 1 then just as many rows, as the maxrows% most frequent factors are shown. Say if maxrows is set to 0.8 then as many rows are shown, that the highest cumulative relative frequency is the first going beyond 0.8.
digits	integer. With how many digits should the relative frequencies be formatted? Default is 3.
dprobs	a vector with the probabilities for the chisq.test of the days. If this is left to NULL (default) then a uniform distribution will be used.
mprobs	a vector with the probabilities for the chisq.test of the months. If this is left to NULL (default) then the distribution of days will be used (p = c(31/365, 28/365, 31/365, ...).
plotit	boolean. Should a plot be created? The factor is plotted with the factor interface of PlotDesc . Default is FALSE.
...	further argument to be passed to methods.

[Desc](#), [PlotDesc](#)

Examples

```
Desc(d.pizza$date)
```

Desc.factor

Describe a Factor, an Ordered Factor Or a Character Vector

Description

This function produces a rich description of a factor, containing length, number of NAs, number of levels and detailed frequencies of all levels. The order of the frequency table can be chosen between descending/ascending frequency, labels or levels. For ordered factors the order default is "level". Character vectors are treated as unordered factors.

Usage

```
## S3 method for class 'factor'
Desc(x, main = NULL, ord = c("desc", "asc", "name", "level"),
     maxrows = 12, digits = 3, plotit = getOption("plotit", FALSE), ...)

## S3 method for class 'ordered'
Desc(x, main = NULL, ...)

## S3 method for class 'character'
Desc(x, main = NULL, ...)
```

Arguments

x	a single factor, an ordered factor or a character vector to be described.
main	the caption of the output. If this is set to NULL (which is the default) the name of the factor and its class will be printed. Use NA if no caption should be printed at all.
ord	the order for the frequency table. Factors (and character vectors) are by default ordered by their descending frequencies, ordered factors by their natural order. If a character e.g. should be ordered alphabetically, set ord to name.
maxrows	numeric value. Defines the maximum number of rows to be reported. For factors with lots of levels it is often not interesting to see all the levels. Default is hence set to 12 most frequent ones (resp. the first ones if ord is set to levels or names). If maxrows is < 1 it will be interpreted as percentage. Then just as many rows, as the maxrows% most frequent factors will be shown. If maxrows is set to 0.8, then the number of rows is fixed so, that the highest cumulative relative frequency is the first one going beyond 0.8.
digits	integer. With how many digits should the relative frequencies be formatted? Default is 3.
plotit	boolean. Should a plot be created? Default is FALSE. The factor is plotted with PlotDesc.factor .
...	further argument to be passed to methods. For ordered factors and character vectors they are passed to Desc.factor.

Details

Desc.char converts x to a factor and processes x as factor.

Desc.ordered does nothing more than changing the standard order for the frequencies to its intrinsic order, which means order "level" instead of "desc" in the factor case.

Value

A list containing the following components:

length	the length of the vector
n	the valid entries (NAs are excluded)
NAs	number of NAs
levels	number of levels
unique	number of unique values. Note that need not be the same, as there might be empty levels. Of course unique values can never be less than the number of levels.
dupes	boolean saying whether there are any duplicates in the vector.
frq	a data.frame of absolute and relative frequencies given by Freq

Author(s)

Andri Signorell <andri@signorell.net>

# ordered factor
Desc(d.diamonds$clarity)

# just the 5 first groups of the factor
Desc(d.diamonds$colour, maxrows = 5)

# just as many rows, as the most frequent 80% of the factor levels use
Desc(d.diamonds$colour, maxrows = 0.8)
```

Desc.flags*Describe a Set of Dichotomous Variables*

Description

Dichotomous variables can easily be condensed in one graphical representation. Desc for a set of flags (=dichotomous variables) calculates the frequencies, a binomial confidence intervall and produces a kind of dotplot with error bars.

Usage

```
## S3 method for class 'flags'  
Desc(x, i = 1, plotit = getOption("plotit", FALSE), ...)  
Flags(x)
```

Arguments

x a data.frame
i
plotit
...

Details

Motivation for this function is, that dichotomous variable in general do not contain intense information. Therefore it makes sense to condense the description of sets of dichotomous variables.

Value

no results are returned.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[Desc](#)

Examples

```
# None so far
```

 Desc.formula

Describe Variables by Groups

Description

Formula interface for describing data by groups.

Usage

```
## S3 method for class 'formula'
Desc(formula, data = parent.frame(), subset,
      plotit = getOption("plotit", FALSE), ...)
```

Arguments

formula	a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
data	an optional matrix or data frame containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used.
plotit	boolean. Should a plot be created? The plot type will be chosen according to the classes of variables (roughly following a numeric-numeric, numeric-categorical, categorical-categorical logic). Default is FALSE.
...	further argument to be passed to methods.

Details

The formula interface accepts the formula operators +, :, *, I(), 1 and evaluates any function. The left hand side and right hand side of the formula are evaluated the same way. The variable pairs are processed in dependency of their classes by the functions [DescFactFact](#), [DescNumFact](#), [DescFactNum](#) and [DescNumNum](#).

Value

just printed summary, no value returned

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
# univariate evaluation of temperature and driver
Desc(temperature + driver ~ 1, data=d.pizza, digits=1)

# temperature by driver
Desc(temperature ~ driver, data=d.pizza, digits=1)

# functions are evaluated
Desc(I(temperature^2) + sqrt(temperature) ~ interaction(driver, area), data=d.pizza, digits=1)
```

Desc.integer	<i>Describe an integer variable</i>
--------------	-------------------------------------

Description

Describing an integer, means typically count data, is sometimes the same as describing an ordered factor, and sometimes, when there are many levels, it is like describing a numeric value.

Usage

```
## S3 method for class 'integer'
Desc(x, main = NULL, maxrows = 12, freq = NULL,
      digits = 3, plotit = getOption("plotit", FALSE), ...)
```

Arguments

x	a single integer vector to be described.
main	the caption for the output.
maxrows	integer. This indicates, up to how many levels the detailed frequencies should be reported. Default is 12. Set maxlevels to NA, if no restriction is to be applied, say the frequency table should contain all existing levels.
freq	logical, indicating if a frequency table should be plotted. Default is NULL, which means a frequency table will be printed, if there are less than 13 unique values. Else there will be a high-low description produced by HighLow.
digits	integer. With how many digits should the relative frequencies be formatted? Default is 3.
plotit	boolean. Should a plot be created? The vector would be plotted by means of PlotDesc.numeric , which again basically is PlotFdist . Default is FALSE.
...	further argument to be passed to methods.

Details

A horizontal barplot would be suitable as well here.

Value

A list containing the following components:

length	the length of the vector (n + NAs).
n	the valid entries (NAs are excluded)
NAs	number of NAs
unique	number of unique values.
0s	number of zeros
mean	arithmetic mean
MeanSE	standard error of the mean, as calculated by MeanSE .
quant	a table of quantiles, as calculated by quantile (x, probs = c(.05, .10, .25, .5, .75, .9, .95), na
sd	standard deviation
vcoef	coefficient of variation: mean(x) / sd(x)
mad	median absolute deviation (mad)
IQR	interquartile range
skew	skewness, as calculated by Skew .
kurt	kurtosis, as calculated by Kurt .
highlow	the lowest and the highest values, reported with their frequencies in brackets, if > 1.
frq	a data.frame of absolute and relative frequencies given by Freq if maxlevels > unique values in the vector.

Author(s)

Andri Signorell <andri@signorell.net>

Desc(d.pizza$count, maxlevels=15)

# Result object
res <- Desc(d.pizza$count, maxlevels=15)
res
```

Desc.logical

Describe a dichotomous variable

Description

Description of a dichotomous variable. This can either be a boolean vector, a factor with two levels or a numeric variable with only two unique values.

Usage

```
## S3 method for class 'logical'
Desc(x, main = NULL, digits = 3,
      conf.level = 0.95, plotit = getOption("plotit", FALSE), ...)
```

Arguments

x	the dichotomous vector to be described.
main	the caption for the output.
digits	integer. With how many digits should the relative frequencies be formatted? Default is 3.
conf.level	confidence level of the interval.
plotit	boolean. Should a plot be created? The plot looks like a horizontal bar plot. Default is FALSE.
...	the dots are passed to the table command within Desc.logical.

Details

The confidence levels for the relative frequencies are calculated by [BinomCI](#), method "Wilson" on a confidence level defined by conf.level.

Value

A list containing the following components:

length	the length of the vector (n + NAs).
n	the valid entries (NAs are excluded)
NAs	number of NAs
unique	number of unique values.
frq	a data.frame of absolute and relative frequencies given by Freq if maxlevels > unique values in the vector.

Author(s)

Andri Signorell <andri@signorell.net>

Desc.numeric	<i>Describe a numeric vector</i>
--------------	----------------------------------

Description

This reports a rich description of a numeric vector, consisting of the most common descriptive measures for location and variability.

Usage

```
## S3 method for class 'numeric'
Desc(x, main = NULL, highlow = TRUE, plotit = getOption("plotit", FALSE), ...)
```

Arguments

x	a single numeric vector to be described.
main	the caption for the output.
highlow	boolean. Should the highest and the lowest values be reported. This is usually a good idea and so the default is TRUE.
plotit	boolean. Should a plot be created? The vector would be plotted by means of PlotDesc.numeric , which again basically is PlotFdist . Default can be defined by option "plotit", if it does not exist then it's set to FALSE.
...	further argument to be passed to methods.

Details

The plot function used here is [PlotFdist](#).

Value

A list containing the following components:

length	the length of the vector (n + NAs).
n	the valid entries (NAs are excluded)
NAs	number of NAs
unique	number of unique values.
0s	number of zeros
mean	arithmetic mean
meanSE	standard error of the mean, as calculated by MeanSE .
quant	a table of quantiles, as calculated by quantile with probs set to c(.05, .10, .25, .5, .75, .9, .95).
sd	standard deviation
vcoef	coefficient of variation: mean(x) / sd(x)
mad	median absolute deviation (mad)

IQR	interquartile range
skew	skewness, as calculated by Skew .
kurt	kurtosis, as calculated by Kurt .
highlow	the lowest and the highest values, reported with their frequencies in brackets, if > 1.

Author(s)

Andri Signorell <andri@signorell.net>

Desc(d.pizza$temperature)

# contains all results of:
quantile(d.pizza$temperature, na.rm=TRUE)
```

Desc.table	<i>Describe a n-dimensional Contingency Table</i>
------------	---

Description

A 2-dimensional table will be described with it's relative frequencies, a short summary containing the total cases, the dimensions of the table, chi-square tests and some association measures as phi-coefficient, contingency coefficient and Cramer's V.

Tables with higher dimensions will simply be printed as flat table, with marginal sums for the first and for the last dimension.

Usage

```
## S3 method for class 'table'
Desc(x, main = NULL, rfrq = NULL,
      margins = c(1, 2), plotit = getOption("plotit", FALSE),
      verbose = c("medium", "low", "high"), ...)

## S3 method for class 'matrix'
Desc(x, main = NULL, rfrq = NULL,
      margins = c(1,2), plotit = getOption("plotit", FALSE),
      verbose = c("medium", "low", "high"), ...)
```

Arguments

<code>x</code>	a n-dimensional table or matrix
<code>main</code>	the main caption for the output.
<code>rfrq</code>	a string with 3 characters, each of them being 1 or 0, defining which percentages should be reported. The first position is interpreted as total percentages, the second as row percentages and the third as column percentages. "011" hence produces a table output with row and column percentages. If set to NULL <code>rfrq</code> is defined in dependency of <code>verbose</code> (<code>verbose = "low"</code> sets <code>rfrq</code> to "000" and else to "111", latter meaning all percentages will be reported.)
<code>margins</code>	a vector, consisting out of 1 and/or 2. Defines the margin sums to be included. Row margins are reported if <code>margins</code> is set to 1. Set it to 2 for column margins and <code>c(1,2)</code> for both. Default is NULL (none).
<code>plotit</code>	logical. Should a plot be created? The table will be plotted by PlotDesc.table , which creates two mosaicplots. Default is FALSE.
<code>verbose</code>	character defining the verbosity of the reported results. One out of <code>c("medium", "low", "high")</code> , "medium" being the default. Can be abbreviated.
<code>...</code>	the dots are passed to the function PercTable , allowing to set further arguments like expected values etc.

Details

Note that NAs cannot be handled by this interface, as tables in general come in "as.is", say basically as a matrix without any further information about potentially previously cleared NAs.

Value

no results are returned.

DescTools Palettes	<i>Some Custom Palettes</i>
--------------------	-----------------------------

Description

Some more custom palettes.

Usage

```

PalDescTools(pal, n = 100)

PalTibco()
PalHelsana()
PalRedToBlack(n = 100)
PalRedBlackGreen(n = 100)
PalSteeblueWhite(n = 100)
PalRedWhiteGreen(n = 100)

hblue
hred
horange
hgreen
hyellow

```

Arguments

pal	name or number of the palette. One of RedToBlack (1), RedBlackGreen (2), SteeblueWhite (3), RedWhiteGreen (4), RedWhiteBlue1 (5), RedWhiteBlue2 (6), Helsana (7), Tibco (8)
n	integer, number of colors for the palette.

Details

hblue and hred are 2 constants, pointing to the red and blue from the palette PalHelsana.

Value

a vector of colors

Author(s)

Andri Signorell <andri@signorell.net>

DescWrd

Use Word as Reporting Tool for Describing Data

Description

Calculates descriptive statistics for x and uses Word as reporting tool.

Usage

```
## Default S3 method:
DescWrd(x, wrd, main = deparse(substitute(x)), ...)

## S3 method for class 'data.frame'
DescWrd(x, wrd, main = NULL, enum = TRUE, ...)

## S3 method for class 'list'
```

```
DescWrd(x, wrd, main = NULL, enum = TRUE, ...)

## S3 method for class 'formula'
DescWrd(formula, data = parent.frame(), subset = TRUE, wrd, ...)
```

Arguments

<code>x</code>	the object to be described.
<code>main</code>	the title of the description or a vector with the main titles for the description of the variables. If this is left blank, the title will be composed as: number - variablename (class(es)).
<code>enum</code>	logical, determining if the number should be included or not. Default is TRUE. The numbers may be redundant or inconsistent, if a Word report with enumerated headings is created.
<code>wrd</code>	the pointer to a word instance. Can be a new one, created by <code>GetNewWrd()</code> or an existing one, created by <code>GetCurrWrd()</code> . Default is the last created pointer stored in <code>getOption("lastWord")</code> .
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.
<code>data</code>	an optional matrix or data frame containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>...</code>	further argument to be passed to methods.

Details

This function is not thought of being directly run by the enduser. It will normally be called automatically, when a pointer to a Word instance is passed to the function [Desc](#). However `DescWrd` takes some more specific arguments concerning the Word output (like font or fontsize), which can make it necessary to call the function directly.

## End(Not run)

```

DivCoef

Rao's diversity coefficient also called quadratic entropy

Description

Calculates Rao's diversity coefficient within samples.

Usage

```
DivCoef(df, dis, scale)
```

Arguments

df	a data frame with elements as rows, samples as columns, and abundance, presence-absence or frequencies as entries
dis	an object of class dist containing distances or dissimilarities among elements. If dis is NULL, Gini-Simpson index is performed.
scale	a logical value indicating whether or not the diversity coefficient should be scaled by its maximal value over all frequency distributions.

Value

Returns a data frame with samples as rows and the diversity coefficient within samples as columns

Note

This function was previously published as `divc()` in the **ade4** package and has been integrated here without logical changes.

Author(s)

Sandrine Pavoine <pavoine@biomserv.univ-lyon1.fr>

# data(ecomor)
# dtaxo <- dist.taxo(ecomor$taxo)
# DivCoef(ecomor$habitat, dtaxo)

# data(humDNAm)
# DivCoef(humDNAm$samples, sqrt(humDNAm$distances))
```

DivCoefMax	<i>Maximal value of Rao's diversity coefficient also called quadratic entropy</i>
------------	---

Description

For a given dissimilarity matrix, this function calculates the maximal value of Rao's diversity coefficient over all frequency distribution. It uses an optimization technique based on Rosen's projection gradient algorithm and is verified using the Kuhn-Tucker conditions.

Usage

```
DivCoefMax(dis, epsilon, comment)
```

Arguments

<code>dis</code>	an object of class <code>dist</code> containing distances or dissimilarities among elements.
<code>epsilon</code>	a tolerance threshold : a frequency is non null if it is higher than <code>epsilon</code> .
<code>comment</code>	a logical value indicating whether or not comments on the optimization technique should be printed.

Value

Returns a list

value	the maximal value of Rao's diversity coefficient.
vectors	a data frame containing four frequency distributions : sim is a simple distribution which is equal to $\frac{D1}{1^t D1}$, pro is equal to $\frac{z}{1^t z 1}$, where z is the nonnegative eigenvector of the matrix containing the squared dissimilarities among the elements, met is equal to z^2 , num is a frequency vector maximizing Rao's diversity coefficient.

## End(Not run)
```

DrawAnnulus

Draw One or Several Annuli

Description

Draw an annulus (or a sequence of annuli) with given center coordinates, fill and border colors on an existing plot using classical graphics.

Usage

```
DrawAnnulus(x = 0, y = x, radius.in = 1, radius.out = 2, nv = 100,
            border = par("fg"), col = par("bg"), lty = par("lty"),
            lwd = par("lwd"), plot = TRUE)
```

Arguments

<code>x, y</code>	a vector (or scalar) of xy-coordinates of the center(s).
<code>radius.in</code>	a vector (or scalar) of the inner radius of the annulus(i).
<code>radius.out</code>	a vector (or scalar) of the outer radius of the annulus(i).
<code>nv</code>	number of vertices to draw the circles. Default is 100.
<code>border</code>	color for the border(s). The default is <code>par("fg")</code> . Use <code>border = NA</code> to omit borders. If there are shading lines, <code>border = TRUE</code> means use the same colour for the border as for the shading lines.
<code>col</code>	color(s) to fill or shade the annulus with. The default <code>NA</code> (or also <code>NULL</code>) means do not fill, i.e., draw transparent rectangles, unless density is specified.
<code>lty</code>	line type for borders and shading; defaults to "solid".
<code>lwd</code>	line width for borders and shading.
<code>plot</code>	logical. If <code>TRUE</code> the structure will be plotted. If <code>FALSE</code> only the xy-points are calculated and returned. Use this option if you want to combine several geometric structures to a single polygon.

Details

All geometric arguments are recycled if necessary.

Value

DrawAnnulus invisibly returns a list of the calculated coordinates for all shapes.

Author(s)

Andri Signorell <andri@signorell.net>

```

DrawAnnulusSector	<i>Draw a Sector of an Annulus</i>
-------------------	------------------------------------

Description

Draw one or more annulus sectors with given centers, radii, angles, fill- and border colors on an existing plot using classical graphics.

Usage

```
DrawAnnulusSector(x = 0, y = x, radius.in = 1, radius.out = 2,
                  angle.beg = 0, angle.end = pi, nv = 100,
                  border = par("fg"), col = par("bg"), lty = par("lty"),
                  lwd = par("lwd"), plot = TRUE)
```

Arguments

<code>x, y</code>	a vector (or scalar) of xy-coordinates of the center(s).
<code>radius.in</code>	a vector (or scalar) of the inner radius of the annulus(i).
<code>radius.out</code>	a vector (or scalar) of the outer radius of the annulus(i).
<code>angle.beg</code>	a vector (or scalar) of the starting angle(s). The sectors are built counterclockwise.
<code>angle.end</code>	a vector (or scalar) of the ending angle(s).
<code>nv</code>	number of vertices to draw the arcs.
<code>border</code>	color for borders. The default is <code>par("fg")</code> . Use <code>border = NA</code> to omit borders. If there are shading lines, <code>border = TRUE</code> means use the same colour for the border as for the shading lines.
<code>col</code>	color(s) to fill or shade the annulus sector with. The default NA (or also NULL) means do not fill (say draw transparent).
<code>lty</code>	line type for borders and shading; defaults to "solid".
<code>lwd</code>	line width for borders and shading.
<code>plot</code>	logical. If TRUE the structure will be plotted. If FALSE only the points are calculated and returned. Use this if you want to combine several geometric structures to a single polygon.

Value

DrawAnnulusSector invisibly returns a list of the calculated coordinates for all shapes.

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
par(mfrow=c(1,2))

angles <- seq( 0,2 * pi, pi/4) # the angles
mycol <- rainbow(8)           # colors of the sector annuli
d <- 0.1                      # the gap between the sectors in radians

plot(1:10, type="n", asp=1, xlab="", ylab="")
res <- sapply( 1:(length(angles)-1),
  function(i) DrawAnnulusSector(x = 6, y = 6, radius.in = 2, radius.out = 3,
    angle.beg = angles[i] + d/2, angle.end = angles[i+1] - d/2, col = mycol[i])
)

# Produce a clockplot
x <- c(15,9,75,90,1,1,11,5,9,8,33,11,11,20,14,13,10,28,33,21,24,25,11,33)
# plot clockwise, starting from 12 o'clock
angles <- (rev(seq(0,2*pi, pi/12) + pi/2))

Canvas(xlim=c(-100,100), main="Number of visitors to web site for each hour of a day")
PolarGrid(nr=c(0,90), ntheta=24, rlabels=NA, alabels=c(6:0, 23:7) )
DrawAnnulusSector(radius.in=0, radius.out=x, angle.beg = angles[-1],
  angle.end = angles[-length(angles)], col=rainbow(24))
```

DrawArc

Draw Elliptic or Circular Arc(s)

Description

Draw one or more elliptic or circular arcs from `angle.beg` to `angle.end` on an existing plot using classic graphics.

Usage

```
DrawArc(x = 0, y = x, radius.x = 1, radius.y = radius.x,
  angle.beg = 0, angle.end = pi, nv = 100,
  col = par("col"), lty = par("lty"), lwd = par("lwd"),
  plot = TRUE)
```

Arguments

<code>x, y</code>	a vector (or scalar) of xy-coordinates of the center(s) of the arc(s).
<code>radius.x</code>	a scalar or a vector giving the semi-major axis of the ellipse for the arc(s)
<code>radius.y</code>	a scalar or a vector giving the semi-minor axis of the ellipse for the arc(s). Default is <code>radius.x</code> which will result in a circle arc with <code>radius.x</code> .
<code>angle.beg</code>	a scalar or a vector of starting angles in radians.
<code>angle.end</code>	a scalar or a vector of ending angles in radians.
<code>nv</code>	number of vertices used to plot the arc. Scalar or vector.
<code>col</code>	color for the arc(s). Scalar or vector.
<code>lty</code>	line type used for drawing.
<code>lwd</code>	line width used for drawing.
<code>plot</code>	logical. If TRUE the structure will be plotted. If FALSE only the xy-points are calculated and returned. Use this if you want to combine several geometric structures to a single polygon.

Details

All parameters are recycled if necessary.

Be sure to use an aspect ratio of 1 as shown in the example to avoid distortion.

Value

`DrawArc` invisibly returns a list of the calculated coordinates for all shapes.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

Examples

```
curve(sin(x), 0, pi, col="blue", asp=1)
DrawArc( x = pi/2, y = 0, radius.x = 1, angle.beg = pi/4, angle.end = 3*pi/4, col="red")
```

DrawBand

Draw Confidence Band

Description

Draw a (confidence) band. Just a wrapper for `polygon`.

Usage

```
DrawBand(x, y, col = SetAlpha("grey", 0.5), border = NA)
```

Arguments

<code>x</code>	a vector or a matrix with x coordinates for the band. If x is given as matrix it must be a $2 \times n$ matrix and the second column will be reversed. x will be recycled in the case y is a 2dimensional matrix.
<code>y</code>	a vector or a matrix with y coordinates for the band. If y is given as matrix it must be a $2 \times n$ matrix and the second column will be reversed. y will be recycled in the case x is a 2dimensional matrix.
<code>col</code>	the color of the band.
<code>border</code>	the border color of the band.

[polygon](#)

Examples

```
set.seed(18)
x <- rnorm(15)
y <- x + rnorm(15)

new <- seq(-3, 3, 0.5)
pred.w.plim <- predict(lm(y ~ x), newdata=data.frame(x=new), interval="prediction")
pred.w.clim <- predict(lm(y ~ x), newdata=data.frame(x=new), interval="confidence")

plot(y ~ x)
DrawBand(y = c(pred.w.plim[,2], rev(pred.w.plim[,3])),
  x=c(new, rev(new)), col= SetAlpha("grey90", 0.5))
DrawBand(y = c(pred.w.clim[,2], rev(pred.w.clim[,3])),
  x=c(new, rev(new)), col= SetAlpha("grey80", 0.5))

abline(lm(y~x), col="brown")
```

DrawBezier

Draw a Bezier Curve

Description

Draw a Bezier curve.

Usage

```
DrawBezier(x = 0, y = x, nv = 100, col = par("col"), lty = par("lty"),
  lwd = par("lwd"), plot = TRUE)
```

Arguments

<code>x, y</code>	a vector of xy-coordinates to define the Bezier curve. Should at least contain 3 points.
<code>nv</code>	number of vertices to draw the curve.
<code>col</code>	color(s) for the curve. Default is <code>par("fg")</code> .
<code>lty</code>	line type for borders and shading; defaults to "solid".
<code>lwd</code>	line width for borders and shading.
<code>plot</code>	logical. If TRUE the structure will be plotted. If FALSE only the xy-points are calculated and returned. Use this if you want to combine several geometric structures to a single polygon.

Details

Bezier curves appear in such areas as mechanical computer aided design (CAD). They are named after P. Bezier, who used a closely related representation in Renault's UNISURF CAD system in the early 1960s (similar, unpublished, work was done by P. de Casteljau at Citroen in the late 1950s and early 1960s). The 1970s and 1980s saw a flowering of interest in Bezier curves, with many CAD systems using them, and many important developments in their theory. The usefulness of Bezier curves resides in their many geometric and analytical properties. There are elegant and efficient algorithms for evaluation, differentiation, subdivision of the curves, and conversion to other useful representations. (See: Farin, 1993)

Value

DrawBezier invisibly returns a list of the calculated coordinates for all shapes.

```
Canvas(xlim=c(0,1))
grid()
DrawBezier( x=c(0,0.5,1), y=c(0,0.5,0), col="blue", lwd=2)
DrawBezier( x=c(0,0.5,1), y=c(0,1,0), col="red", lwd=2)
DrawBezier( x=c(0,0.25,0.5,0.75,1), y=c(0,1,1,1,0), col="darkgreen", lwd=2)
```

DrawCircle

Draw a Circle

Description

Draw one or several circle on an existing plot.

Usage

```
DrawCircle(x = 0, y = x, radius = 1, rot = 0, nv = 100,
           border = par("fg"), col = par("bg"), lty = par("lty"),
           lwd = par("lwd"), plot = TRUE)
```

Arguments

<code>x, y</code>	a vector (or scalar) of xy-coordinates for the center(s) of the circle(s).
<code>radius</code>	a scalar or a vector giving the radius of the circle(s)
<code>rot</code>	rotation angle for the geometric structure in radians.
<code>nv</code>	number of vertices to draw the circle.
<code>border</code>	color for annulus borders. The default is <code>par("fg")</code> . Use <code>border = NA</code> to omit borders.
<code>col</code>	color(s) to fill or shade the circle(s) with. The default <code>NA</code> (or also <code>NULL</code>) means do not fill, i.e., draw transparent rectangles, unless density is specified.
<code>lty</code>	line type for borders and shading; defaults to <code>"solid"</code> .
<code>lwd</code>	line width for borders and shading.
<code>plot</code>	logical. If <code>TRUE</code> the structure will be plotted. If <code>FALSE</code> only the points are calculated and returned. Use this option if you want to combine several geometric structures to a polygon.

Details

All geometric arguments will be recycled.

DrawCircle(col=NA)

```

DrawEllipse

*Draw an Ellipse***Description**

Draw one or several ellipses on an existing plot.

Usage

```

DrawEllipse(x = 0, y = x, radius.x = 1, radius.y = 0.5, rot = 0,
            nv = 100, border = par("fg"), col = par("bg"),
            lty = par("lty"), lwd = par("lwd"), plot = TRUE)

```

Arguments

x, y	the x and y co-ordinates for the centre(s) of the ellipse(s).
radius.x	a scalar or a vector giving the semi-major axis of the ellipse.
radius.y	a scalar or a vector giving the semi-minor axis of the ellipse.
rot	angle of rotation in radians.
nv	number of vertices to draw the ellipses.
border	color for borders. The default is par("fg"). Use border = NA to omit borders.
col	color(s) to fill or shade the annulus sector with. The default NA (or also NULL) means do not fill (say draw transparent).
lty	line type for borders and shading; defaults to "solid".
lwd	line width for borders and shading.

`plot` logical. If TRUE the structure will be plotted. If FALSE only the points are calculated and returned. Use this if you want to combine several geometric structures to a single polygon.

Details

Use [DegToRad](#) if you want to define rotation angle in degrees.

Value

The function invisibly returns a list of the calculated coordinates for all shapes.

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
par(mfrow=c(1,2))

Canvas()
DrawEllipse(rot = c(1:3) * pi/3, col=SetAlpha(c("blue","red","green"), 0.5) )

plot(cars)
m <- var(cars)
eig <- eigen(m)
eig.val <- sqrt(eig$values)
eig.vec <- eig$vectors

DrawEllipse(x=mean(cars$speed), y=mean(cars$dist), radius.x=eig.val[1] , radius.y=eig.val[2]
, rot=acos(eig.vec[1,1]), border="blue", lwd=3)
```

DrawRegPolygon

Draw Regular Polygon(s)

Description

Draw a regular polygon with n corners. This is the workhorse function for drawing regular polygons. Drawing a circle can be done by setting the vertices to a value of say 100.

Usage

```
DrawRegPolygon(x = 0, y = x, radius.x = 1, radius.y = radius.x, rot = 0,
nv = 3, border = par("fg"), col = par("bg"), lty = par("lty"),
lwd = par("lwd"), plot = TRUE)
```

Arguments

<code>x, y</code>	a vector (or scalar) of xy-coordinates of the center(s) of the regular polygon(s).
<code>radius.x</code>	a scalar or a vector giving the semi-major axis of the ellipse for the polygon(s).
<code>radius.y</code>	a scalar or a vector giving the semi-minor axis of the ellipse for the polygon(s). Default is <code>radius.x</code> which will result in a polygon with <code>radius.x</code> .
<code>rot</code>	angle of rotation in radians.
<code>nv</code>	number of vertices to draw the polygon(s).
<code>border</code>	color for borders. The default is <code>par("fg")</code> . Use <code>border = NA</code> to omit borders.
<code>col</code>	color(s) to fill or shade the shape with. The default <code>NA</code> (or also <code>NULL</code>) means do not fill (say draw transparent).
<code>lty</code>	line type for borders and shading; defaults to <code>"solid"</code> .
<code>lwd</code>	line width for borders and shading.
<code>plot</code>	logical. If <code>TRUE</code> the structure will be plotted. If <code>FALSE</code> only the points are calculated and returned. Use this if you want to combine several geometric structures to a polygon.

Details

All geometric arguments will be recycled.

Value

The function invisibly returns a list of the calculated coordinates for all shapes.

```

 Dummy

Generate Dummy Codes for a Factor

Description

Generates a matrix of dummy codes (class indicators) for a given factor.

Usage

```
Dummy(x, method = c("treatment", "sum", "helmert", "poly", "full"), base = 1)
```

Arguments

x	factor or vector of classes for cases.
method	defines the method of the contrasts being formed. Can be one out of "treatment", "sum", "helmert", "poly", "full", whereas "treatment" is the default one. Abbreviations are accepted. The option "full" returns a full set of class indicators, say a dummy factor for EACH level of x. Note that this would be redundant for lm and friends!
base	an integer specifying which group is considered the baseline group.

Value

a matrix with the dummy codes. The rows correspond to the number of elements in x and the columns to it's levels.

DunnettTest

Dunnett's Test for Comparing Several Treatments With a Control

Description

Performs Dunnett's test for comparing several treatments with a control.

Usage

```
DunnettTest(x, ...)
```

Default S3 method:

```
DunnettTest(x, g, control = NULL, conf.level = 0.95, ...)
```

```
## S3 method for class 'formula'
DunnettTest(formula, data, subset, na.action,
             control = NULL, conf.level = 0.95, ...)
```

Arguments

<code>x</code>	a numeric vector of data values, or a list of numeric data vectors.
<code>g</code>	a vector or factor object giving the group for the corresponding elements of <code>x</code> . Ignored if <code>x</code> is a list.
<code>control</code>	the level of the control group against which the others should be tested.
<code>conf.level</code>	confidence level of the interval.
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

`DunnettTest` does the post hoc pairwise multiple comparisons procedure.

If `x` is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, `g` is ignored, and one can simply use `DunnettTest(x)` to perform the test. If the samples are not yet contained in a list, use `DunnettTest(list(x, ...))`.

Otherwise, `x` must be a numeric data vector, and `g` must be a vector or factor object of the same length as `x` giving the group for the corresponding elements of `x`.

Value

A list of class `c("PostHocTest")`, containing one matrix named after the control with columns `diff` giving the difference in the observed means, `lwr.ci` giving the lower end point of the interval, `upr.ci` giving the upper end point and `pval` giving the p-value after adjustment for the multiple comparisons.

There are print and plot methods for class `"PostHocTest"`. The plot method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.

DunnTest

*Dunn's Test of Multiple Comparisons***Description**

Performs Dunn's test of multiple comparisons using rank sums.

Usage

```
DunnTest(x, ...)
```

Default S3 method:

```
DunnTest(x, g,
        method = c("holm", "hochberg", "hommel", "bonferroni", "BH",
                    "BY", "fdr", "none"),
        out.list = TRUE, ...)
```

S3 method for class 'formula'

```
DunnTest(formula, data, subset, na.action,
        method = c("holm", "hochberg", "hommel", "bonferroni", "BH",
                    "BY", "fdr", "none"),
        out.list = TRUE, ...)
```

S3 method for class 'DunnTest'

```
print(x, digits = getOption("digits"), ...)
```

Arguments

<code>x</code>	a numeric vector of data values, or a list of numeric data vectors.
<code>g</code>	a vector or factor object giving the group for the corresponding elements of <code>x</code> . Ignored if <code>x</code> is a list.
<code>method</code>	the method for adjusting p-values for multiple comparisons. The function is calling <code>p.adjust</code> and this parameter is directly passed through.
<code>out.list</code>	logical, indicating if the results should be printed in list mode or as a square matrix. Default is <code>list</code> (<code>TRUE</code>).
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>digits</code>	controls the number of digits to print.
<code>...</code>	further arguments to be passed to or from methods.

Details

DunnTest does the post hoc pairwise multiple comparisons procedure appropriate to follow the rejection of a Kruskal-Wallis test. The Kruskal-Wallis test, being a non-parametric analog of the one-way ANOVA, is an omnibus test of the null hypothesis that none of k groups stochastically dominate one another. Dunn's test is constructed in part by summing jointly ranked data. The rank sum test, itself a non-parametric analog of the unpaired t-test, is possibly intuitive, but inappropriate as a post hoc pairwise test, because (1) it fails to retain the dependent ranking that produced the Kruskal-Wallis test statistic, and (2) it does not incorporate the pooled variance estimate implied by the null hypothesis of the Kruskal-Wallis test.

If `x` is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, `g` is ignored, and one can simply use `DunnTest(x)` to perform the test. If the samples are not yet contained in a list, use `DunnTest(list(x, ...))`.

Otherwise, `x` must be a numeric data vector, and `g` must be a vector or factor object of the same length as `x` giving the group for the corresponding elements of `x`.

Value

A list with class "DunnTest" containing the following components:

<code>res</code>	an array containing the mean rank differencens and the according p-values
------------------	---

DurbinWatsonTest

Durbin-Watson Test

Description

Performs the Durbin-Watson test for autocorrelation of disturbances.

Usage

```
DurbinWatsonTest(formula, order.by = NULL,
                  alternative = c("greater", "two.sided", "less"),
                  iterations = 15, exact = NULL, tol = 1e-10, data = list())
```

Arguments

formula	a symbolic description for the model to be tested (or a fitted "lm" object).
order.by	Either a vector z or a formula with a single explanatory variable like ~ z. The observations in the model are ordered by the size of z. If set to NULL (the default) the observations are assumed to be ordered (e.g., a time series).
alternative	a character string specifying the alternative hypothesis.

iterations	an integer specifying the number of iterations when calculating the p-value with the "pan" algorithm.
exact	logical. If set to FALSE a normal approximation will be used to compute the p value, if TRUE the "pan" algorithm is used. The default is to use "pan" if the sample size is < 100.
tol	tolerance. Eigenvalues computed have to be greater than tol to be treated as non-zero.
data	an optional data frame containing the variables in the model. By default the variables are taken from the environment which DurbinWatsonTest is called from.

Details

The Durbin-Watson test has the null hypothesis that the autocorrelation of the disturbances is 0. It is possible to test against the alternative that it is greater than, not equal to, or less than 0, respectively. This can be specified by the `alternative` argument.

Under the assumption of normally distributed disturbances, the null distribution of the Durbin-Watson statistic is the distribution of a linear combination of chi-squared variables. The p-value is computed using the Fortran version of Applied Statistics Algorithm AS 153 by Farebrother (1980, 1984). This algorithm is called "pan" or "gradsol". For large sample sizes the algorithm might fail to compute the p value; in that case a warning is printed and an approximate p value will be given; this p value is computed using a normal approximation with mean and variance of the Durbin-Watson test statistic.

Examples can not only be found on this page, but also on the help pages of the data sets [bondyield](#), [currencysubstitution](#), [growthofmoney](#), [moneydemand](#), [unemployment](#), [wages](#).

For an overview on R and econometrics see Racine & Hyndman (2002).

Value

An object of class "htest" containing:

statistic	the test statistic.
p.value	the corresponding p-value.
method	a character string with the method used.
data.name	a character string with the data name.

Note

This function was previously published as `dwtest` in the **lmtest** package and has been integrated here without logical changes.

```

Entropy

Shannon Entropy and Mutual Information

Description

Computes Shannon entropy and the mutual information of two variables. The entropy quantifies the expected value of the information contained in a vector. The mutual information is a quantity that measures the mutual dependence of the two random variables.

Usage

```
Entropy(x, y = NULL, base = 2, ...)
```

```
MutInf(x, y, base = 2, ...)
```

Arguments

x	a vector or a matrix of numerical or categorical type. If only x is supplied it will be interpreted as contingency table.
y	a vector with the same type and dimension as x. If y is not NULL then the entropy of <code>table(x, y, ...)</code> will be calculated.
base	base of the logarithm to be used, defaults to 2.
...	further arguments are passed to the function <code>table</code> , allowing i.e. to set <code>useNA</code> .

Details

The Shannon entropy equation provides a way to estimate the average minimum number of bits needed to encode a string of symbols, based on the frequency of the symbols.

It is given by the formula $H = -\sum(\pi \log(\pi))$ where π is the probability of character number i showing up in a stream of characters of the given "script".

The entropy is ranging from 0 to Inf.

Value

a numeric value.

ErrBars

Add Error Bars to an Existing Plot

Description

Add Error Bars to an Existing Plot.

Usage

```

ErrBars(from, to = NULL, pos = NULL, mid = NULL, horiz = FALSE, col = par("fg"),
        lty = par("lty"), lwd = par("lwd"), code = 3, length = 0.05,
        pch = NA, cex.pch = par("cex"), col.pch = par("fg"), bg.pch = par("bg") )

```

Arguments

from	coordinates of points from which to draw (the lower end of the error bars).
to	coordinates of points to which to draw (the upper end of the error bars).
pos	numeric, position of the error bars. This will either be the x-coordinate in case of vertical error bars and the y-coordinate in case of horizontal error bars.

<code>mid</code>	numeric, position of midpoints. Defaults to the mean of <code>from</code> and <code>to</code> .
<code>horiz</code>	logical, determining whether horizontal error bars are needed (default is <code>FALSE</code>).
<code>col</code>	the line color.
<code>lty</code>	the line type.
<code>lwd</code>	line width.
<code>code</code>	integer code, determining kind of arrows to be drawn. If <code>code = 1</code> an arrowhead is drawn at $(x0[i], y0[i])$ and if <code>code = 2</code> an arrowhead is drawn at $(x1[i], y1[i])$. If <code>code = 3</code> (default) a head is drawn at both ends of the arrow. Unless <code>length = 0</code> , when no head is drawn.
<code>length</code>	the length of the end lines.
<code>pch</code>	plotting character for the midpoints. No points will be plotted if this is set to <code>NA</code> , which is the default.
<code>cex.pch</code>	the character extension for the plotting characters. Default is <code>par("cex")</code> .
<code>col.pch</code>	the color of the plotting characters. Default is <code>par("fg")</code> .
<code>bg.pch</code>	the background color of the plotting characters (if <code>pch</code> is set to 21:25). Default is <code>par("bg")</code> .
<code>...</code>	the dots are passed to the arrows function.

Details

EtaSq

*Effect size calculations for ANOVAs***Description**

Calculates eta-squared, partial eta-squared and generalized eta-squared

Usage

```
EtaSq(x, type = 2, anova = FALSE)
```

```
## S3 method for class 'lm'
EtaSq(x, type = 2, anova = FALSE)
```

```
## S3 method for class 'aovlist'
EtaSq(x, type = 2, anova = FALSE)
```

Arguments

x	An analysis of variance (aov, aovlist) object.
type	What type of sum of squares to calculate? EtaSq.aovlist requires type=1.
anova	Should the full ANOVA table be printed out in addition to the effect sizes?

Details

Calculates the eta-squared, partial eta-squared, and generalized eta-squared measures of effect size that are commonly used in analysis of variance. The input x should be the analysis of variance object itself. For between-subjects designs, generalized eta-squared equals partial eta-squared. The reported generalized eta-squared for repeated-measures designs assumes that all factors are manipulated, i.e., that there are no measured factors like gender (see references).

For unbalanced designs, the default in EtaSq is to compute Type II sums of squares (type=2), in keeping with the Anova function in the car package. It is possible to revert to the Type I SS values (type=1) to be consistent with anova, but this rarely tests hypotheses of interest. Type III SS values (type=3) can also be computed. EtaSq.aovlist requires type=1.

Value

If anova=FALSE, the output for EtaSq.lm is an M x 2 matrix, for EtaSq.aovlist it is an M x 3 matrix. Each of the M rows corresponds to one of the terms in the ANOVA (e.g., main effect 1, main effect 2, interaction, etc), and each of the columns corresponds to a different measure of effect size. Column 1 contains the eta-squared values, and column 2 contains partial eta-squared values. Column 3 contains the generalized eta-squared values. If anova=TRUE, the output contains additional columns containing the sums of squares, mean squares, degrees of freedom, F-statistics and p-values. For EtaSq.aovlist, additional columns contain the error sum of squares and error degrees of freedom corresponding to an effect term.

Exec*Execute a Command Given As String*

Description

Execute a piece of code.

Usage

```
Exec(x)
```

Arguments

x the code to be executed

Details

This is just a wrapper to eval and parse, but easier to remember...

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[eval](#), [parse](#)

Examples

```
A <- "This"
B <- "is"
C <- "a text"
for(s in LETTERS[1:3])
  Exec(gettextf("print(%s)", s))
```

ExpFreq*Expected frequencies*

Description

Calculate the expected frequencies of an n-way table assuming independence.

Usage

```
ExpFreq(x, freq = c("abs", "rel"))
```

Arguments

x	a table.
freq	indicates, whether absolute or relative frequencies should be computed. Can either be "abs" or "rel". Partial matching is supported.

Value

A table with either the absolute or the relative expected frequencies.

Note

This is a copy of the function `independence_table` in **vcd**.

Author(s)

David Meyer <David.Meyer@R-project.org>

See Also

[chisq.test](#)

Examples

```
ExpFreq(Titanic)
ExpFreq(UCBAdmissions, freq="r")
```

Explore

Interactive Graphical Data Explorer

Description

Use RStudio's manipulator to explore a data.frame by dynamically creating xy-scatterplots, box-plots and others. Numerical descriptions can as well be produced on the fly.

Usage

```
Explore(x)
```

Arguments

x	the data.frame to be explored.
---	--------------------------------

Details

This function helps to get rid of the afterwards superfluous R-code created while exploring a dataset.

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
## Not run:  
Explore(d.pizza)  
  
## End(Not run)
```

Factorize*Prime Factorization of Integers*

Description

Compute the prime factorization(s) of integer(s) *n*.

Usage

```
Factorize(n)
```

Arguments

n vector of integers to factorize.

Details

works via [Primes](#), currently in a cheap way, sub-optimal for large composite *n*.

Value

A named [list](#) of the same length as *n*, each element a 2-column matrix with column "p" the prime factors and column~"m" their respective exponents (or multiplities), i.e., for a prime number *n*, the resulting matrix is `cbind(p = n, m = 1)`.

Author(s)

Martin Maechler, Jan. 1996.

See Also

[Primes](#).

For factorization of moderately or really large numbers, see the **gmp** package, and its [factorize\(\)](#).

Examples

```
Factorize(47)  
Factorize(seq(101, 120, by=2))
```

FctArgs*Retrieve a Functions' Arguments*

Description

Retrieve a functions' arguments and default values in a list.

Usage

```
FctArgs(name, sort = FALSE)
```

Arguments

name	name of the function.
sort	logical. Should the function arguments be sorted? Defaults to FALSE.

Value

a data.frame with the default in the first columns and with row.names as argument names.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[formalArgs](#) just returns the name of the arguments, but not their defaults.

Examples

```
formalArgs(PlotFdist)

# compare:
FctArgs(PlotFdist)
```

Fibonacci*Fibonacci Numbers*

Description

Generates Fibonacci numbers.

Usage

```
Fibonacci(n)
```

Arguments

n	nonnegative integer or vector of nonnegative integers.
---	--

Details

Generates the n-th Fibonacci number, whereas `Fibonacci(0) = 0`.

Value

A single integer, or a vector of integers.

Author(s)

Andri Signorell <andri@signorell.net>

References

http://en.wikipedia.org/wiki/Fibonacci_number

Examples

```
Fibonacci(0)           # 1
Fibonacci(2)           # 2
Fibonacci(0:3)          # 0 1 1 2

# Golden ratio
F <- Fibonacci(1:25)    # ... 75025 121393
f25 <- F[25]/F[24]      # 1.618033989
phi <- (sqrt(5) + 1)/2
abs(f25 - phi)           # 7.945178e-11

# Fibonacci numbers without iteration
fibonacci <- function(n) {
  phi <- (sqrt(5) + 1)/2
  fib <- (phi^(n+1) - (1-phi)^(n+1)) / (2*phi - 1)
  round(fib)
}

fibonacci(30:33)        # 1346269 2178309 3524578 5702887
```

FindColor

Get Color on a Defined Color Range

Description

Find a color on a defined color range depending on the value of x. This is helpful for colorcoding numeric values.

Usage

```
FindColor(x, cols = rev(heat.colors(100)),
          min.x = min(pretty(x)), max.x = max(pretty(x)),
          all.inside = FALSE)
```

Arguments

<code>x</code>	numeric.
<code>cols</code>	a vector of colors.
<code>min.x</code>	the x-value to be used for the left edge of the first color.
<code>max.x</code>	the x-value to be used for the right edge of the last color.
<code>all.inside</code>	logical; if true, the returned indices are coerced into 1, ..., N-1, i.e., 0 is mapped to 1 and N to N-1.

Details

For the selection of colors the option `rightmost.closed` in the used function `findInterval` is set to TRUE. This will ensure that all values on the right edge of the range are assigned a color. How values outside the boundaries of `min.x` and `max.x` should be handled can be controlled by `all.inside`. Set this value to TRUE, if those values should get the colors at the edges or set it to FALSE, if they should remain white (which is the default).

Note that `findInterval` closes the intervals on the left side, e.g. `[0, 1)`. This option can't be changed. Consequently will x-values lying on the edge of two colors get the color of the bigger one.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[findInterval](#)

Examples

```
Canvas(7, main="Use of function FindColor()")

# get some data
x <- c(23, 56, 96)
# get a color range from blue via white to red
cols <- colorRampPalette(c("blue","white","red"))(100)
ColorLegend(x="bottomleft", cols=cols, labels=seq(0, 100, 10), cex=0.8)

# and now the color coding of x:
(xcols <- FindColor(x, cols, min.x=0, max.x=100))

# this should be the same as
cols[x+1]

# how does it look like?
y0 <- c(-5, -2, 1)
text(x=1, y=max(y0)+2, labels="Color coding of x:")
text(x=1.5, y=y0, labels=x)
DrawRegPolygon(x=3, y=y0, nv=4, rot=pi/4, col=xcols)
text(x=6, y=y0, labels=xcols)
```

FindCorr*Determine highly correlated variables*

Description

This function searches through a correlation matrix and returns a vector of integers corresponding to columns to remove to reduce pair-wise correlations.

Usage

```
FindCorr(x, cutoff = .90, verbose = FALSE)
```

Arguments

x	A correlation matrix
cutoff	A numeric value for the pair-wise absolute correlation cutoff
verbose	A boolean for printing the details

Details

The absolute values of pair-wise correlations are considered. If two variables have a high correlation, the function looks at the mean absolute correlation of each variable and removes the variable with the largest mean absolute correlation.

There are several function in the **subselect** package ([leaps](#), [genetic](#), [anneal](#)) that can also be used to accomplish the same goal.

Value

A vector of indices denoting the columns to remove. If no correlations meet the criteria, `numeric(0)` is returned.

Author(s)

Original R code by Dong Li, modified by Max Kuhn

FindCorr(m, verbose = TRUE)
m[, FindCorr(m)]
```

FisherZ

Fisher r to z and z to r and confidence intervals

Description

Convert a correlation to a z score or z to r using the Fisher transformation or find the confidence intervals for a specified correlation.

Usage

```
FisherZ(rho)
FisherZInv(z)
CorCI(rho, n, conf.level = 0.95, alternative = c("two.sided", "less", "greater"))
```

Arguments

rho	the Pearson's correlation coefficient
z	a Fisher z transformed value
n	sample size used for calculating the confidence intervals
alternative	is a character string, one of "greater", "less", or "two.sided", or the initial letter of each, indicating the specification of the alternative hypothesis. "greater" corresponds to positive association, "less" to negative association.
conf.level	confidence level for the returned confidence interval, restricted to lie between zero and one.

Details

The sampling distribution of Pearson's r is not normally distributed. Fisher developed a transformation now called "Fisher's z-transformation" that converts Pearson's r's to the normally distributed variable z'. The formula for the transformation is:

$$z_r = \tanh^{-1} = \frac{1}{2} \log \left(\frac{1+r}{1-r} \right)$$

Value

z value corresponding to r (in FisherZ)
 r corresponding to z (in FisherZInv)
 rho, lower and upper confidence intervals (CorCI)

Author(s)

William Revelle <revelle@northwestern.edu>,
 slight modifications Andri Signorell <andri@signorell.net> based on R-Core code

r <- seq(0, .9, .1)
rc <- t(sapply(r, CorCI, n=n))
t <- r * sqrt(n-2) / sqrt(1-r^2)
p <- (1 - pt(t, n-2)) / 2

r.rc <- data.frame(r=r, z=FisherZ(r), lower=rc[,2], upper=rc[,3], t=t, p=p)

round(r.rc, 2)
```

FixToTab

Text to Table

Description

Convert a text to a table by using complete columns of spaces (or any other separator) as delimiting point.

Usage

```
FixToTab(txt, sep = " ", delim = "\t", trim = TRUE, header = TRUE)
```

Arguments

txt	the text to be partitioned. Works best, if txt is a matrix.
sep	the separator to use. Will frequently be " ".
delim	the new delimiter to insert. (default tab)
trim	logical. Should the separated text be trimmed from whitespace? Defaults to TRUE.
header	logical. Should the first line be interpreted as header?

Details

Only a complete appearance of the separator character in the same position over all rows will be accepted as column delimiter.

Value

a matrix of the separated text.

Author(s)

Andri Signorell <andri@signorell.net>

[StrChop](#)

Examples

```
# let's get some tabbed text
txt <- matrix(capture.output(Titanic[, , 2, 1]))
FixToTab(txt[-1,])
```

Format

Format Numbers and Dates

Description

Formatting numbers in R often degenerates into a major intellectual challenge for us little guys. We have several functions available and quite often it's hard to work out which one to use, when a special option is needed. This function wraps those functions and tries to offer a simpler, but still flexible interface.

Usage

```
Format(x, digits = NULL, sci = getOption("scipen"), big.mark="",
       leading = NULL, zero.form = NULL, na.form = NULL,
       fmt = NULL, align = "left", width = NULL, ...)

## S3 method for class 'matrix'
Format(x, digits = NULL, sci = getOption("scipen"), big.mark="",
       leading = NULL, zero.form = NULL, na.form = NULL,
       fmt = NULL, align = "left", width = NULL, ...)

## Default S3 method:
Format(x, digits = NULL, sci = getOption("scipen"), big.mark="",
       leading = NULL, zero.form = NULL, na.form = NULL,
       fmt = NULL, align = "left", width = NULL, ...)
```

Arguments

<code>x</code>	an atomic numerical, typically a vector of real numbers or a matrix of numerical values.
<code>digits</code>	integer, the desired number of digits after the decimal point. Unlike <code>formatC</code> you will always get this number of digits even if the last digit is 0.
<code>sci</code>	integer. The power of 10 to be set when deciding to print numeric values in fixed or exponential notation. Fixed notation will be preferred unless the number is larger than 10^{scipen} . If just one value is set it will be used for the left border $10^{(-\text{scipen})}$ as well as for the right one (10^{scipen}). A negative and a positive value can also be set independently.
<code>big.mark</code>	character; if not empty used as mark between every <code>big.interval</code> decimals before (hence <code>big</code>) the decimal point.
<code>leading</code>	character string that can be used for setting leading zeros. "000" would make sure that at least 3 digits on the left side will be printed. Setting <code>leading</code> to "" will yield results like ".452" for 0.452. The default <code>NULL</code> will leave the numbers as they are.
<code>zero.form</code>	character, string specifying how zeros should be formatted specially. Useful for pretty printing 'sparse' objects. If set to <code>NULL</code> (default) no special action will be taken.
<code>na.form</code>	character, string specifying how NAs should be formatted specially. If set to <code>NULL</code> (default) no special action will be taken.
<code>fmt</code>	a format string, allowing to flexibly define special formats. See Details.
<code>align</code>	one out of "left", "right", "center", "dec". The values will be aligned left (default), right, center or at the decimal point.
<code>width</code>	integer, the defined width of the strings.
<code>...</code>	further arguments to be passed to or from methods.

Details

The argument `fmt` can be used for defining several formats.

`dates` Dates can be formatted with the format codes `d`, `m` and `y` for day, month or year. Repeating the specific code defines the degree of abbreviation:

- `d` day of the month without leading zero (1 - 31)
- `dd` day of the month with leading zero (01 - 31)
- `ddd` . . . abbreviated name for the day of the week (e.g. Mon) in the current user's language
- `dddd` . . full name for the day of the week (e.g. Monday) in the current user's language
- `m` month without leading zero (1 - 12)
- `mm` month with leading zero (01 - 12)
- `mmm` . . . abbreviated month name (e.g. Jan) in the current user's language
- `mmm.` . . full month name (e.g. January) in the current user's language
- `y` year without century, without leading zero (0 - 99)
- `yy` year without century, with leading zero (00 - 99)
- `yyyy` . . year with century. For example: 2005

`scientific` `fmt = "e"` forces scientific representation of `x`. The number of digits, alignment

and zero values will be respected.

- percent Setting `fmt = "%"` will divide the given number by 100 and append the %-sign (without separator).
- p-value `fmt = "p"` will wrap the function [format.pval](#).
- significance The significance representation of a p-value consisting of * and . will be produced by setting `fmt = "*"`. The breaks are set according to the used defaults e.g. in `lm` as
`[0, 0.001] = ***`
`(0.001, 0.01] = **`
`(0.01, 0.05] = *`
`(0.05, 0.1] = .`
`(0.1, 1] =`

Value

the formatted values as characters.

If `x` was a matrix, then the result will also be a matrix. (Hope this will not surprise you...)

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
Format(as.Date(c("2014-11-28", "2014-1-2")), fmt="ddd, d mmmm yyyy")
```

```
x <- pi * 10^(-10:10)
```

```
Format(x, digits=3, fmt="%", sci=NA)
```

```
Format(x, digits=4, sci=4, leading = "drop", width=9, align="dec")
```

```
# format a matrix
```

```
m <- matrix(runif(100), nrow=10,  
            dimnames=list(LETTERS[1:10], LETTERS[1:10]))
```

```
Format(m, digits=1)
```

Frac

Return the Fractional Part of a Numeric Value

Description

Return the fractional part of a numeric value.

Usage

```
Frac(x, dpwr = NA)
```

Arguments

x the numeric value (or a vector of numerics), whose fractional part is to be calculated.

dpwr if dpwr is not missing, the fractional part will be multiplied by 10^{dpwr} and returned rounded to integer. Defaults to NA.

Value

return the fractional part of x.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[Ndec](#)

Examples

```
x <- rnorm(5)*100
x
Frac(x)

# multiply by 10^4
Frac(x, dpwr=4)
```

Freq

Frequency Table

Description

Calculates absolute and relative frequencies of a vector x. Continuous (numeric) variables will be cut using the same logic as used by the function [hist](#). Categorical variables will be aggregated by [table](#). The result will contain single and cumulative frequencies for both, absolute values and percentages.

Usage

```
Freq(x, breaks = hist(x, plot = FALSE)$breaks, include.lowest = TRUE,
     ord = c("level", "desc", "asc", "name"),
     useNA = c("no", "ifany", "always"), ...)

## S3 method for class 'Freq'
print(x, digits = 3, ...)
```

Arguments

<code>x</code>	the variable to be described, can be any atomic type.
<code>breaks</code>	either a numeric vector of two or more cut points or a single number (greater than or equal to 2) giving the number of intervals into which <code>x</code> is to be cut. Default taken from the function <code>hist()</code> . This is ignored if <code>x</code> is not of numeric type.
<code>include.lowest</code>	logical, indicating if an <code>x[i]</code> equal to the lowest (or highest, for <code>right = FALSE</code>) "breaks" value should be included. Ignored if <code>x</code> is not of numeric type.
<code>ord</code>	how should the result be ordered? Default is "level", other choices are 'by frequency' ("descending" or "ascending") or 'by name of the levels' ("name"). The argument can be abbreviated. This is ignored if <code>x</code> is numeric.
<code>useNA</code>	one out of "no", "ifany", "always". Defines whether to include extra NA levels in the table. Defaults to "no" which is the <code>table()</code> default too.
<code>digits</code>	integer, determining the number of digits used to format the relative frequencies.
<code>...</code>	further arguments are passed to the function <code>cut()</code> . Use <code>dig.lab</code> to control the format of numeric group names. Use the argument <code>right</code> to define if the intervals should be closed on the right (and open on the left) or vice versa. In <code>print.Freq</code> the dots are not used.

Details

If `breaks` is specified as a single number, the range of the data is divided into breaks pieces of equal length, and then the outer limits are moved away by 0.1% of the range to ensure that the extreme values both fall within the break intervals. (If `x` is a constant vector, equal-length intervals are created that cover the single value.)

Value

an object of type "Freq", which is basically a data.frame with 5 columns (earning a specific print routine), containing the following components:

<code>level</code>	factor. The levels of the grouping variable.
<code>freq</code>	integer. The absolute frequencies.
<code>perc</code>	numeric. The relative frequencies (percent).
<code>cumfreq</code>	integer. The cumulative sum of the absolute frequencies.
<code>cumperc</code>	numeric. The cumulative sum of the relative frequencies.

Examples

```
data(d.pizza)

# result is a data.frame
d.freq <- Freq(d.pizza$price)
d.freq

# it is printed by default with 3 digits for the percent values,
# but the number of digits can be defined in the print function
print(d.freq, digits=5)

# sorted by frequency
Freq(d.pizza$driver, ord="desc")

# sorted by name, including NAs
Freq(d.pizza$driver, ord="name", useNA="ifany")
```

GCD, LCM

*Greatest Common Divisor and Least Common Multiple***Description**

Calculates the greatest common divisor (GCD) and least common multiple (LCM).

Usage

```
GCD(x)
LCM(x)
```

Arguments

x a vector of integers.

Details

The computation is based on the Euclidean algorithm without using the extended version. The greatest common divisor for all numbers in the integer vector x will be computed (the multiple GCD).

Value

A numeric (integer) value.

Note

The following relation is always true:

$$n * m = \text{GCD}(n, m) * \text{LCM}(n, m)$$

Note

This functions stem from the library **numbers** and are a combination of GCD, LCM, mGCD, mLCM.

GCD(c(12, 10))
GCD(c(46368, 75025)) # Fibonacci numbers are relatively prime to each other

LCM(c(12, 10))
LCM(c(46368, 75025)) # = 46368 * 75025

GCD(c(2, 3, 5, 7) * 11)
GCD(c(2*3, 3*5, 5*7))
LCM(c(2, 3, 5, 7) * 11)
LCM(c(2*3, 3*5, 5*7))
```

GetAllSubsets

Get All Subsets out of a List of Elements

Description

Returns a list with all the subsets that can be built based on the elements given in x.
The number of elements used in the combinations can be limited by setting min.n and max.n.

Usage

```
GetAllSubsets(x, min.n = 1, max.n = length(x))
```

Arguments

x	a vector with elements
min.n	the minimum count of elements to be drawn. This defaults to 1.
max.n	the maximum count of elements to be drawn. Default is "all elements in x".

Value

a list with the subsets.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[GetPairs](#), [PairApply](#)

Examples

```
x <- LETTERS[1:6]

GetAllSubsets(x)

#get all sets of size 2 and 3
GetAllSubsets(x, min.n = 2, max.n = 3)
```

GetCurrWrd

Get a Handle to a Running Word Instance

Description

Look for a running Word instance and return its handle. NULL is returned if nothing's found.

Usage

```
GetCurrWrd()
GetCurrXL()
```

Value

a handle (pointer) to the running Word, resp. Excel instance.

Note

Closing an instance does not update the value of the pointer. So it may contain an invalid address. Whether the pointer is still valid can be checked by [IsValidWrd](#).

Note

This does unfortunately not work with RDCOMClient (but it would with rcom)! Any better idea out there?

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[GetNewWrd](#), [IsValidWrd](#)

Examples

```
## Not run: # Windows-specific example

x <- rnorm(100)

wrd <- GetCurrWrd()

if(IsValidWrd(wrd)){
  Desc(x, wrd=wrd)
} else {
```

```

    print("GetCurrWrd: no running word instance found...")
  }

  ## End(Not run)

```

GetNewPP

Create a new PowerPoint Instance

Description

Start a new instance of PowerPoint and return its handle. A new presentation with one empty slide will be created. The handle is needed for addressing the presentation afterwards.

GetCurrPP will look for a running PowerPoint instance and return its handle. NULL is returned if nothing's found.

Usage

```
GetNewPP(visible = TRUE, template = "Normal")
```

```
GetCurrPP()
```

Arguments

visible	logical, should PowerPoint made visible? Defaults to TRUE.
template	the name of the template to be used for creating a new presentation.

Value

a handle (pointer) to the created PowerPoint instance.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[GetNewXL](#), [GetNewWrd](#), [PpPlot](#)

Examples

```

## Not run: # Windows-specific example
# get a handle to a new PowerPoint instance
# (this will be used further to export R-Objects to PowerPoint)
pp <- GetNewPP()

## End(Not run)

```

GetNewWrd

*Create a new Word Instance***Description**

Start a new instance of Word and return its handle. This handle allows controlling word afterwards. WrdKill ends a running Word task.

Usage

```
GetNewWrd(visible = TRUE, template = "Normal", header = FALSE,
          main = "Descriptive report")
```

```
WrdKill()
```

```
createCOMReference(ref, className)
```

Arguments

visible	logical, should Word made visible? Defaults to TRUE.
template	the name of the template to be used for creating a new document.
header	logical, should a caption and a list of contents be inserted? Default is FALSE.
main	the main title of the report
ref	the S object that is an external pointer containing the reference to the COM object
className	the name of the class that is "suggested" by the caller

Details

RDCOMClient reveals the whole VBA-world of MS-Word. So generally speaking any VBA code can be run from R. It might be a good idea to record a macro and rewrite the VB-code in R.

Here's a list of some frequently used commands.
Let's assume:

```
wrd <- GetNewWrd()
sel <- wrd$Selection()
```

new document	wrd[["Documents"]]\$Add(template, FALSE, 0), template is the templatename.
open	wrd[["Documents"]]\$Open(Filename="C:/MyPath/MyDocument.docx").
save	wrd\$ActiveDocument()\$SaveAs2(FileName="P:/MyFile.docx")
quit word	wrd\$quit()
kill word task	WrdKill kills a running word task (which might not be ended with quit.)
normal text	Use WrdText which offers many arguments as fontname, size, color, alignment etc. WrdText("Lorem ipsum dolor sit amet, consetetur", fontname="Arial", fontsize=10, col=wdConst\$wdColorRed)
simple text	sel\$TypeText("sed diam nonumy eirmod tempor invidunt ut labore")
heading 1	WrdCaption("My Word-Story", stylename = wdConst\$wdStyleHeading1)

heading 2	WrdCaption("My Word-Story", stylename = wdConst\$wdStyleHeading2)
insert R output	WrdText(capture.output(str(d.diamonds)))
pagebreak	sel\$InsertBreak(wdConst\$wdPageBreak)
move cursor right	sel\$MoveRight(Unit=wdConst\$wdCharacter, Count=2, Extend=wdConst\$wdExtend)
goto end	sel\$EndKey(Unit=wdConst\$wdStory)
pagesetup	sel[["PageSetup"]][["Bottommargin"]] <- 4 * 72
add bookmark	wrd[["ActiveDocument"]][["Bookmarks"]]\$Add("myBookmark")
goto bookmark	sel\$GoTo(wdConst\$wdGoToBookmark, 0, 0, "myBookmark")
show document map	wrd[["ActiveWindow"]][["DocumentMap"]] <- TRUE
insert table	WrdTable()
create table	WrdInsTab() which allows to define the table's geometry
insert caption	sel\$InsertCaption(Label="Abbildung", TitleAutoText="InsertCaption", Title="My Title")
tables of figures	wrd\$ActiveDocument()\$TablesOfFigures()\$Add(Range=sel\$range(), Caption="Abbildung")

createCOMReference is just a wrapper for RDCOMClient::createCOMReference, as the function is not visible, if RDCOMClient is only used by required namespace.

Value

a handle (pointer) to the created Word instance.

Note

Note that the list of contents has to be refreshed by hand after inserting text (if inserted by header = TRUE).

Author(s)

Andri Signorell <andri@signorell.net>

Desc(d.pizza[,1:4], wrd=wrd)

# enumerate all bookmarks in active document
for(i in 1:wrd[["ActiveDocument"]][["Bookmarks"]]$count()){
  print(wrd[["ActiveDocument"]][["Bookmarks"]][i]$Name())
}

## End(Not run)
```

GetNewXL

Create a new Excel Instance

Description

Start a new instance of Excel and return its handle. This is needed to address XL afterwards.

Usage

```
GetNewXL(visible = TRUE)
```

Arguments

`visible` logical, should Excel made visible? Defaults to TRUE.

Details

Here's a list of some frequently used commands.
Let's assume:

```
x1 <- GetNewXL()
```

```
workbooks  x1$workbooks()$count()
quit excel  x1$quit()
```

Author(s)

Andri Signorell <andri@signorell.net>

See Also

```

GetPairs

Get All Pairs out of one or two Sets of Elements

Description

Returns all combinations of 2 out of the elements in `x` or `x` and `y` (if defined). Combinations of the same elements will be dropped (no replacing).

Usage

```
GetPairs(x, y = NULL)
```

Arguments

x a vector of elements

y a vector of elements, need not be same dimension as x. If y is not NULL then all combination x and y are returned.

Details

If y = NULL then all combination of 2 out of x are returned.
 If y is defined then all combinations of x and y are calculated.

Value

GetPairs returns a data.frame with 2 columns X1 and X2.

Author(s)

Andri Signorell <andri@signorell.net>

[combn](#), [expand.grid](#), [outer](#), [lower.tri](#)

Examples

```
GetPairs(letters[1:4])
GetPairs(x = letters[1:4], y = LETTERS[1:2])

# get all pairs of combinations between factors and numerics out of a data.frame
GetPairs(which(sapply(d.pizza, IsNumeric)), which(sapply(d.pizza, is.factor)))
```

Gini

Gini Coefficient

Description

Compute the Gini coefficient.

Usage

```
Gini(x, n = rep(1, length(x)), unbiased = TRUE,
     conf.level = NA, R = 1000, type = "bca", na.rm = FALSE)
```

Arguments

<code>x</code>	a vector containing at least non-negative elements. The result will be NA, if <code>x</code> contains negative elements.
<code>n</code>	a vector of frequencies (weights), must be same length as <code>x</code> .
<code>unbiased</code>	logical. In order for <code>G</code> to be an unbiased estimate of the true population value, calculated gini is multiplied by $n/(n - 1)$. Default is TRUE. (See Dixon, 1987)
<code>conf.level</code>	confidence level for the confidence interval, restricted to lie between 0 and 1. If set to TRUE the bootstrap confidence intervals are calculated. If set to NA (default) no confidence intervals are returned.
<code>R</code>	number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case <code>R</code> would be a vector of integers where each component gives the number of resamples from each of the rows of weights. This is ignored if no confidence intervals are to be calculated.
<code>type</code>	character string representing the type of interval required. The value should be one out of the <code>c("norm", "basic", "stud", "perc" or "bca")</code> . This argument is ignored if no confidence intervals are to be calculated.
<code>na.rm</code>	logical. Should missing values be removed? Defaults to FALSE.

Details

The small sample variance properties of the Gini coefficient are not known, and large sample approximations to the variance of the coefficient are poor (Mills and Zandvakili, 1997; Glasser, 1962; Dixon et al., 1987), therefore confidence intervals are calculated via bootstrap re-sampling methods (Efron and Tibshirani, 1997).

Two types of bootstrap confidence intervals are commonly used, these are percentile and bias-corrected (Mills and Zandvakili, 1997; Dixon et al., 1987; Efron and Tibshirani, 1997). The bias-corrected intervals are most appropriate for most applications. This is set as default for the `type` argument ("bca"). Dixon (1987) describes a refinement of the bias-corrected method known as 'accelerated' - this produces values very closed to conventional bias corrected intervals.

(Iain Buchan (2002) *Calculating the Gini coefficient of inequality*, see: http://www.statsdirect.com/help/nonparametric_methods/gini_coefficient.htm)

Value

If `conf.level` is set to NA then the result will be

a single numeric value

and if a `conf.level` is provided, a named numeric vector with 3 elements:

<code>gini</code>	Gini coefficient
<code>lwr.ci</code>	lower bound of the confidence interval
<code>upr.ci</code>	upper bound of the confidence interval

# perfect balance
Gini(c(10, 10, 10))
```

GiniSimpson	<i>Compute Gini-Simpson Coefficient</i>
-------------	---

Description

Calculate the Gini-Simpson coefficient.

Usage

```
GiniSimpson(x, na.rm = FALSE)
```

Arguments

x	a vector containing at least non-negative elements.
na.rm	logical. Should missing values be removed? Defaults to FALSE.

Details

The original Simpson index λ equals the probability that two entities taken at random from the dataset of interest (with replacement) represent the same type. The Simpson index was introduced in 1949 by Edward H. Simpson to measure the degree of concentration when individuals are classified into types. The same index was rediscovered by Orris C. Herfindahl in 1950. The square root of the index had already been introduced in 1945 by the economist Albert O. Hirschman. As a result, the same measure is usually known as the Simpson index in ecology, and as the Herfindahl index or the Herfindahl-Hirschman index (HHI) in economics.

Its transformation $1 - \lambda$ therefore equals the probability that the two entities represent different types. This measure is also known in ecology as the probability of interspecific encounter (PIE) and the Gini-Simpson index.

Value

a numeric value.

GiniSimpson(x)

# is the same as
1 - Herfindahl(x)

GiniSimpson(c(783, 121, 112, 70, 201, 153, 425, 19, 37, 126, 325, 51, 442, 193, 41))
```

Gmean

*Geometric Mean and Standard Deviation***Description**

Calculates the geometric mean and the geometric standard deviation of a vector x.

Usage

```
Gmean(x, na.rm = FALSE)

Gsd(x, na.rm = FALSE)
```

Arguments

x	a positive numeric vector. An object which is not a vector is coerced (if possible) by as.vector.
na.rm	logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.

Details

The geometric mean and geometric sd are restricted to positive inputs (because otherwise the answer can have an imaginary component). Hence if any argument is negative, then the result is NA. If any argument is zero, then the geometric mean is zero.

It is defined as

$$\sqrt[n]{x_1 \cdot x_2 \cdot x_3 \cdot \dots \cdot x_n}$$

Use [sapply](#) to calculate the measures from data frame, resp. from a matrix.

Value

a numeric value.

sapply(as.data.frame(m), Gmean)
```

GoodmanKruskalGamma *Goodman Kruskal's Gamma*

Description

Calculate Goodman Kruskal's Gamma statistic, a measure of association for ordinal factors in a two-way table.

The function has interfaces for a table (matrix) and for single vectors.

Usage

```
GoodmanKruskalGamma(x, y = NULL, conf.level = NA, ...)
```

Arguments

<code>x</code>	a numeric vector or a contingency table. A matrix will be treated as a table.
<code>y</code>	NULL (default) or a vector with compatible dimensions to <code>x</code> . If <code>y</code> is provided, <code>table(x, y, ...)</code> is calculated.
<code>conf.level</code>	confidence level of the interval. If set to NA (which is the default) no confidence intervals will be calculated.
<code>...</code>	further arguments are passed to the function <code>table</code> , allowing i.e. to set <code>useNA</code> . This refers only to the vector interface.

Details

The estimator of γ is based only on the number of concordant and discordant pairs of observations. It ignores tied pairs (that is, pairs of observations that have equal values of X or equal values of Y). Gamma is appropriate only when both variables lie on an ordinal scale.

It has the range [-1, 1]. If the two variables are independent, then the estimator of gamma tends to be close to zero. For 2×2 tables, gamma is equivalent to Yule's Q ([YuleQ](#)).

Gamma is estimated by

$$G = \frac{P - Q}{P + Q}$$

where P equals twice the number of concordances and Q twice the number of discordances.

Value

a single numeric value if no confidence intervals are requested,
and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

)

GoodmanKruskalGamma(tab, conf.level=0.95)
```

GoodmanKruskalTauA	<i>Goodman Kruskal's Tau a</i>
--------------------	--------------------------------

Description

Calculate Goodman Kruskal's tau-a statistic, a measure of association for ordinal factors in a two-way table.

The function has interfaces for a table (matrix) and for single vectors.

Usage

```
GoodmanKruskalTauA(x, y = NULL, direction = c("row", "column"), conf.level = NA, ...)
```

Arguments

x	a numeric vector or a table. A matrix will be treated as table.
y	NULL (default) or a vector with compatible dimensions to x. If y is provided, <code>table(x, y, ...)</code> is calculated.
direction	direction of the calculation. Can be "row" (default) or "column", where "row" calculates Goodman Kruskal's tau-a (RIC) ("column dependent").
conf.level	confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
...	further arguments are passed to the function <code>table</code> , allowing i.e. to set <code>useNA</code> . This refers only to the vector interface.

Details

Goodman and Kruskal's tau-a is a measure of categorical association which is based entirely on the observed data and possesses a clear interpretation in terms of proportional reduction in error. It gives the probabilities of correctly assigning cases to one set of categories improved by the knowledge of another set of categories. The statistic is asymmetric and yields different results predicting row assignments based on columns than from column assignments based on rows.

Goodman Kruskal's tau-a is computed as

$$\tau_a(C|R) = \frac{P - Q}{\frac{1}{2} \cdot n \cdot (n - 1)}$$

where P equals twice the number of concordances and Q twice the number of discordances. It's range is [0, 1]. Goodman Kruskal tau reduces to ϕ^2 (see: [Phi](#)) in the 2x2-table case.

(Note that Goodman Kruskal tau-a does not take into consideration any ties, which makes it unpractical.)

Value

a single numeric value if no confidence intervals are requested,
and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

Herfindahl

Concentration Measures

Description

Computes the concentration within a vector according to the specified concentration measure.

Usage

```
Herfindahl(x, n = rep(1, length(x)), parameter = 1, na.rm = FALSE)
Rosenbluth(x, n = rep(1, length(x)), na.rm = FALSE)
```

Arguments

x	a vector containing non-negative elements
n	a vector of frequencies (weights), must be same length as x.
parameter	parameter of the concentration measure (if set to NULL the default parameter of the respective measure is used)
na.rm	logical. Should missing values be removed? Defaults to FALSE.

Value

the value of the concentration measure

Note

The same measure is usually known as the Simpson index in ecology, and as the Herfindahl index or the Herfindahl-Hirschman index (HHI) in economics.

Note

These functions were previously published as `conc()` in the **ineq** package and have been integrated here without logical changes. NA and weights support were added.

```

HexToCol

Identify closest match to a color given by a hexadecimal string

Description

Given a color as a hex string `#rrggbb`, find the closest match in the table of known (named) colors.

Usage

```
HexToCol(hexstr, method = "rgb", metric = "euclidean")
```

Arguments

hexstr	a color or a vector of colors specified as hexadecimal string of the form "#rrggbb" or "#rrggbbaa"
method	character string specifying the color space to be used. Can be "rgb" (default) or "hsv".
metric	character string specifying the metric to be used for calculating distances between the colors. Available options are "euclidean" (default) and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.

Details

Finds the color with the minimum squared distance in RGB space.

Value

The colorname(s) of the closest match(es) (if more than one).

HexToRgb	<i>Convert a Hexstring Color to a Matrix With Three Red/Green/Blue Rows</i>
----------	---

Description

Converts a hexstring color to matrix with 3 red/green/blue rows.

Usage

```
HexToRgb(hex)
```

Arguments

hex	a color or a vector of colors specified as hexadecimal string of the form "#rrggbb" or "#rrggbbaa"
-----	--

Value

a matrix with 3 rows.

Author(s)

Andri Signorell <andri@signorell.net>

[HexToCol](#)

Examples

```
HexToRgb(c("#ADD8E6", "#FA1572"))
```

HighLow

Return the Lowest and the Highest Values and Their Frequencies

Description

A printing routine for the highest and the lowest values of x. It enumerates the according values and their frequencies (in brackets).

Usage

```
HighLow(x, nlow = 5, nhigh = nlow, na.rm = FALSE)
```

Arguments

x	a numeric vector or an ordered factor.
nlow	a single integer. The number of the smallest elements of a vector to be printed. Defaults to 5.
nhigh	a single integer. The number of the greatest elements of a vector to be printed. Defaults to the number of nlow.
na.rm	logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.

Details

This is used for describing univariate variables and is interesting for checking the ends of the vector, where in real data often wrong values accumulate.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

Examples

```
cat(HighLow(d.pizza$temperature, na.rm=TRUE))
```

Hmean*Harmonic mean*

Description

Calculates the harmonic mean of a vector `x`.

Usage

```
Hmean(x, na.rm = FALSE)
```

Arguments

<code>x</code>	a positive numeric vector. An object which is not a vector is coerced (if possible) by <code>as.vector</code> .
<code>na.rm</code>	logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.

Details

If any argument is negative, then the result will be NA. If any argument is zero, then the harmonic mean is zero. Otherwise, the harmonic mean is the reciprocal of the arithmetic mean of the reciprocals of the values.

Use [sapply](#) to calculate the measures from data frame, resp. from a matrix.

Value

a numeric value.

Author(s)

Andri Signorell <andri@signorell.net>

```

HmsToSec	<i>Convert h:m:s To/From Seconds</i>
----------	--------------------------------------

Description

HmsToSec - Converts a vector of h:m:s to seconds.

SecToHms - Converts a vector of seconds to h:m:s.

Usage

```
HmsToSec(x)
SecToHms(x, digits = NULL)
```

Arguments

x	A vector of times in h:m:s (for HmsToSec) or seconds (for SecToHms).
digits	the number of digits to use for potential fractions of seconds.

Value

HmsToSec - Returns a vector of times in seconds.

SecToHms - Returns a vector of times in h:m:s format.

SecToHms(c(256, 3456, 56565))
```

HodgesLehmann	<i>Hodges-Lehmann Estimator of Location</i>
---------------	---

Description

Function to compute the Hodges-Lehmann estimator of location in the one sample case.
Simple wrapper to extract the value from the result of [wilcox.test](#).

Usage

```
HodgesLehmann(x, y = NULL, conf.level = NA, na.rm = FALSE)
```

Arguments

<code>x</code>	a numeric vector.
<code>y</code>	an optional numeric vector of data values: as with <code>x</code> non-finite values will be omitted.
<code>conf.level</code>	confidence level of.
<code>na.rm</code>	logical. Should missing values be removed? Defaults to FALSE.

Details

The Hodges-Lehmann estimator is the median of the combined data points and Walsh averages. It is the same as the Pseudo Median returned as a by-product of the function `wilcox.test`. Note that in the two-sample case the estimator for the difference in location parameters does not estimate the difference in medians (a common misconception) but rather the median of the difference between a sample from `x` and a sample from `y`. The confidence interval for the "pseudo median" is extracted from `wilcox.test` (`conf.int = TRUE`).

Value

the Hodges-Lehmann estimator of location as a single numeric value if no confidence intervals are requested,
and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

Author(s)

Andri Signorell <andri@signorell.net>

```

HoeffD

*Matrix of Hoeffding's D Statistics***Description**

Computes a matrix of Hoeffding's (1948) D statistics for all possible pairs of columns of a matrix. D is a measure of the distance between $F(x, y)$ and $G(x)H(y)$, where $F(x, y)$ is the joint CDF of X and Y, and G and H are marginal CDFs. Missing values are deleted in pairs rather than deleting all rows of x having any missing variables. The D statistic is robust against a wide variety of alternatives to independence, such as non-monotonic relationships. The larger the value of D, the more dependent are X and Y (for many types of dependencies). D used here is 30 times Hoeffding's original D, and ranges from -0.5 to 1.0 if there are no ties in the data. `print.HoeffD` prints the information derived by HoeffD. The higher the value of D, the more dependent are x and y.

Usage

```
HoeffD(x, y)
## S3 method for class 'HoeffD'
print(x, ...)
```

Arguments

x	a numeric matrix with at least 5 rows and at least 2 columns (if y is absent), or an object created by HoeffD
y	a numeric vector or matrix which will be concatenated to x
...	ignored

Details

Uses midranks in case of ties, as described by Hollander and Wolfe. P-values are approximated by linear interpolation on the table in Hollander and Wolfe, which uses the asymptotically equivalent Blum-Kiefer-Rosenblatt statistic. For $P < .0001$ or > 0.5 , P values are computed using a well-fitting linear regression function in $\log P$ vs. the test statistic. Ranks (but not bivariate ranks) are computed using efficient algorithms (see reference 3).

Value

a list with elements D, the matrix of D statistics, n the matrix of number of observations used in analyzing each pair of variables, and P, the asymptotic P-values. Pairs with fewer than 5 non-missing values have the D statistic set to NA. The diagonals of n are the number of non-NAs for the single variable corresponding to that row and column.

HotellingsT2Test

Hotelling's T2 Test

Description

Hotelling's T2 test for the one and two sample case.

Usage

```
HotellingsT2Test(X, ...)

## Default S3 method:
HotellingsT2Test(X, Y = NULL, mu = NULL, test = "f",
  na.action = na.fail, ...)

## S3 method for class 'formula'
HotellingsT2Test(formula, na.action = na.fail, ...)
```

Arguments

X	a numeric data frame or matrix.
Y	an optional numeric data frame or matrix for the two sample test. If NULL a one sample test is performed.
mu	a vector indicating the hypothesized value of the mean (or difference in means if a two sample test is performed). NULL represents origin or no difference between the groups.
test	if 'f', the decision is based on the F-distribution, if 'chi' a chi-squared approximation is used.
formula	a formula of the form $X \sim g$ where X is a numeric matrix giving the data values and g a factor with two levels giving the corresponding groups.
na.action	a function which indicates what should happen when the data contain 'NA's. Default is to fail.
...	further arguments to be passed to or from methods.

Details

The classical test for testing the location of a multivariate population or for testing the mean difference for two multivariate populations. When `test = "f"` the F-distribution is used for the test statistic and it is assumed that the data are normally distributed. If the chisquare approximation is used, the normal assumption can be relaxed to existence of second moments. In the two sample case both populations are assumed to have the same covariance matrix.

The formula interface is only applicable for the 2-sample tests.

Value

A list with class 'htest' containing the following components:

statistic	the value of the T2-statistic. (That is the scaled value of the statistic that has an F distribution or a chisquare distribution depending on the value of test).
parameter	the degrees of freedom for the T2-statistic.
p.value	the p-value for the test.
null.value	the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.
alternative	a character string with the value 'two.sided'.
method	a character string indicating what type of test was performed.
data.name	a character string giving the name of the data (and grouping vector).

  teacher = factor(rep(1:2, c(3, 6))),
  satis = c(1, 3, 2, 4, 6, 6, 5, 5, 4),
  know = c(3, 7, 2, 6, 8, 8, 10, 10, 6))

(m1 <- with(math.teach,
  HotellingsT2Test(cbind(satis, know) ~ teacher))
)
```

HuberM	<i>Safe (generalized) Huber M-Estimator of Location</i>
--------	---

Description

(Generalized) Huber M-estimator of location with MAD scale, being sensible also when the scale is zero where [huber\(\)](#) returns an error.

Usage

```
HuberM(x, k = 1.5, mu = median(x), s = mad(x, center = mu),
  na.rm = FALSE, conf.level = NA, ci.type = c("wald", "boot"), ...)
```

Arguments

<code>x</code>	numeric vector.
<code>k</code>	positive factor; the algorithm winsorizes at <code>k</code> standard deviations.
<code>mu</code>	initial location estimator.
<code>s</code>	scale estimator held constant through the iterations.
<code>na.rm</code>	logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.
<code>conf.level</code>	confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
<code>ci.type</code>	The type of confidence interval required. The value should be any subset of the values "classic", "norm", "basic", "stud", "perc" or "bca" ("all" which would compute all five types of intervals, is not supported).
<code>...</code>	the dots are passed to the function boot , when confidence intervalls are calculated.

Details

The standard error is computed using the τ correction factor but no finite sample correction.

Value

If `conf.level` is set to NA then the result will be

a single numeric value

and if a `conf.level` is provided, a named numeric vector with 3 elements:

<code>huberm</code>	the estimate
<code>lwr.ci</code>	lower bound of the confidence interval
<code>upr.ci</code>	upper bound of the confidence interval

Author(s)

Martin Maechler, building on the MASS code mentioned.

HuberM(x, conf.level=0.95, ci.type="boot")

## End(Not run)
```

ICC

*Intraclass Correlations (ICC1, ICC2, ICC3 From Shrout and Fleiss)***Description**

The Intraclass correlation is used as a measure of association when studying the reliability of raters. Shrout and Fleiss (1979) outline 6 different estimates, that depend upon the particular experimental design. All are implemented and given confidence limits.

Usage

```
ICC(ratings, type = c("all", "ICC1", "ICC2", "ICC3", "ICC1k", "ICC2k", "ICC3k"),
    conf.level = NA, na.rm = FALSE)

## S3 method for class 'ICC'
print(x, digits = 3, ...)
```

Arguments

<code>ratings</code>	$n \times m$ matrix or dataframe, k subjects (in rows) m raters (in columns).
<code>type</code>	one out of "all", "ICC1", "ICC2", "ICC3", "ICC1k", "ICC2k", "ICC3k". See details.
<code>conf.level</code>	confidence level of the interval. If set to NA (which is the default) no confidence intervals will be calculated.
<code>na.rm</code>	logical, indicating whether NA values should be stripped before the computation proceeds. If set to TRUE only the complete cases of the ratings will be used. Defaults to FALSE.
<code>x</code>	object to print
<code>digits</code>	number of digits to use in printing
<code>...</code>	further arguments to be passed to or from methods.

Details

Shrout and Fleiss (1979) consider six cases of reliability of ratings done by k raters on n targets.

- ICC1 Each target is rated by a different judge and the judges are selected at random. (This is a one-way ANOVA fixed effects model and is found by $(MSB - MSW)/(MSB + (nr-1)*MSW)$)
- ICC2 A random sample of k judges rate each target. The measure is one of absolute agreement in the ratings. Found as $(MSB - MSE)/(MSB + (nr-1)*MSE + nr*(MSJ-MSE)/nc)$
- ICC3 A fixed set of k judges rate each target. There is no generalization to a larger population of judges. $(MSB - MSE)/(MSB + (nr-1)*MSE)$

Then, for each of these cases, is reliability to be estimated for a single rating or for the average of k ratings? (The 1 rating case is equivalent to the average intercorrelation, the k rating case to the Spearman Brown adjusted reliability.)

ICC1 is sensitive to differences in means between raters and is a measure of absolute agreement.

ICC2 and ICC3 remove mean differences between judges, but are sensitive to interactions of raters by judges.

The difference between ICC2 and ICC3 is whether raters are seen as fixed or random effects.

ICC1k, ICC2k, ICC3K reflect the means of k raters.

The intraclass correlation is used if raters are all of the same "class". That is, there is no logical way of distinguishing them. Examples include correlations between pairs of twins, correlations between raters. If the variables are logically distinguishable (e.g., different items on a test), then the more typical coefficient is based upon the inter-class correlation (e.g., a Pearson r) and a statistic such as alpha or omega might be used.

Value

if method is set to "all", then the result will be

results	A matrix of 6 rows and 8 columns, including the ICCs, F test, p values, and confidence limits
summary	The anova summary table
stats	The anova statistics
MSW	Mean Square Within based upon the anova

if a specific type has been defined, the function will first check, whether no confidence intervals are requested: if so, the result will be the estimate as numeric value

else a named numeric vector with 3 elements

ICCx	estimate (name is the selected type of coefficient)
lwr.ci	lower confidence interval
upr.ci	upper confidence interval

Note

The results for the lower and upper Bounds for ICC(2,k) do not match those of SPSS 9 or 10, but do match the definitions of Shrout and Fleiss. SPSS seems to have been using the formula in McGraw and Wong, but not the errata on p 390. They seem to have fixed it in more recent releases (15).

  6, 1, 3, 2,
  8, 4, 6, 8,
  7, 1, 2, 6,
  10, 5, 6, 9,
  6, 2, 4, 7),
  ncol=4, byrow=TRUE,
  dimnames=list(paste("S", 1:6, sep=""), paste("J", 1:4, sep="")))

sf #example from Shrout and Fleiss (1979)
ICC(sf)
```

identify.formula	<i>Identify points in a plot using a formula.</i>
------------------	---

Description

The function `identify` reads the position of the graphics pointer when the (first) mouse button is pressed. It then searches the coordinates given in `x` and `y` for the point closest to the pointer. If this point is close enough to the pointer, its index will be returned as part of the value of the call.

Usage

```
## S3 method for class 'formula'
identify(formula, data, subset, na.action, ...)
```

Arguments

<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.
<code>data</code>	The data frame from which the formula should be evaluated.
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	Other arguments to be passed to <code>identify</code> .

Details

This function is meant to make it easier to call `identify` after `plot` has been called using a formula and the data argument.

A two dimensional plot must be active and the vectors in `x` and data frame in `data` must correspond to the x- and y-axes and the data of the plot.

Value

If `pos` is `FALSE`, an integer vector containing the indices of the identified points, in the order they were identified. If `pos` is `TRUE`, a list containing a component `ind`, indicating which points were identified and a component `pos`, indicating where the labels were placed relative to the identified points (1=below, 2=left, 3=above, 4=right and 0=no offset, used if `atpen = TRUE`).

```

IdentifyA

Identify Points in Plot Lying within a Rectangle or Polygon

Description

Find all the points lying either in a rectangle area, spanned by an upper left point and a bottom-right point clicked by the user or in a polygon area defined by the user.

Usage

```
IdentifyA(formula, data, subset, poly = FALSE)
```

Arguments

formula	a formula , such as <code>y ~ x</code> specifying x and y values. Here the formula must be entered that was used to create the scatterplot.
data	a data frame (or list) from which the variables in formula should be taken.
subset	an optional vector specifying a subset of observations to be used.
poly	logical. Defines if a polygon or a rectangle should be used to select the points. Default is rectangle. If a polygon should be used, set this argument to TRUE and select all desired points. The polygon will be closed automatically when finished.

Value

Index vector with the points lying within the selected area. The coordinates are returned as text in the attribute "cond".

idx <- IdentifyA(temperature ~ delivery_min, data=d.pizza, poly=TRUE)
points(temperature ~ delivery_min, data = d.pizza[idx,], col="red")

## End(Not run)
```

ImportDlg

Get Path of a Data File to Be Opened

Description

Handling of pathnames is tedious in Windows because of the backslashes, that prevent simple pasting of a copied path into the source code. ImportDlg displays the FileOpen-Dialog for picking a file interactively. When done backslashes in the path are replaced by slashes and the result is being copied into the clipboard, from where it can easily be pasted in any code editor.

Usage

```
ImportDlg(fmt = 1)
```

Arguments

fmt	the format, in which the filename parts should be returned. Default ist path\filename.ext and coded as "\"%path%\%fname%.%fxt%\"". See examples for time saving alternative definitions.
-----	---

Value

ImportDlg() invisibly returns the path of the chosen file in the defined format. The result is additionally being copied to the clipboard.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[file.choose](#)

Examples

```
## Not run:
# choose a file
fn <- ImportDlg()
print(gettextf("You chose the file: %s ", fn))

# the path and filename can as well be nested in a command,
# done here to build a read.table command that can be well inserted into the code:
ImportDlg(fmt="d.%fname% <- read.table(file = \"%path%\\%fname%.%fmt%\",
  header = TRUE, sep = \";\", na.strings = c(\"NA\", \"NULL\"), strip.white = TRUE)\"))

# go to your editor and paste...

## End(Not run)
```

ImportFileDlg

Import File In Foreign Format

Description

Import a file in SPSS, Stata, SAS, Minitab or Systat format interactively.

Usage

```
ImportFileDlg(auto_type = TRUE, env = .GlobalEnv)
```

Arguments

auto_type	determines if the type dialog should be displayed. Default is FALSE, so that if the file extensions are ".sav", ".dta" the appropriate dialog will be called directly.
env	environment in which the dataset should be created.

Details

The imported file will be assigned to the given variablename.

InDots	<i>Is a Specific Argument in the Dots-Arguments?</i>
--------	--

Description

Returns TRUE if a specific named argument was given in the dots.

Usage

```
InDots(..., arg, default)
```

Arguments

...	the dots arguments of the function whose arguments are to be checked.
arg	the name of argument to test for.
default	the default value to return, if the argument arg does not exist in the dots.

Value

the value of the argument, if it exists else the specified default value.

Author(s)

Andri Signorell <andri@signorell.net>

IsDate	<i>Check if an Object is of Type Date</i>
--------	---

Description

Check if the given x is of any known Date type.

Usage

```
IsDate(x, what = c("either", "both", "timeVaries"))
```

Arguments

x	a vector or values to be checked.
what	can be any value out of "either" (default), "both" or "timeVaries".

Details

This checks for many known Date and Time classes: "POSIXt", "POSIXct", "dates", "times", "chron", "Date".

Value

logical vector of the same dimension as x.

Author(s)

Frank E Harrell

IsDichotomous

Test If a Variable Contains Only Two Unique Values

Description

Test if a variable contains only two values, and maybe NAs. The variable does not need to be a numerical value, factors and logicals are supported as well.

Usage

```
IsDichotomous(x)
```

Arguments

x a numeric or integer vector, a logical vector or a factor (ordered and unordered)

Value

TRUE if x contains only two unique values, FALSE else

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
IsDichotomous(sample(10, 5, replace=TRUE))
```

IsEuclid*Is a Distance Matrix Euclidean?*

Description

Confirmation of the Euclidean nature of a distance matrix by the Gower's theorem.
IsEuclid is used in `summary.dist`.

Usage

```
IsEuclid(distmat, plot = FALSE, print = FALSE, tol = 1e-07)
```

Arguments

<code>distmat</code>	an object of class 'dist'
<code>plot</code>	a logical value indicating whether the eigenvalues bar plot of the matrix of the term $-\frac{1}{2}d_{ij}^2$ centred by rows and columns should be displayed
<code>print</code>	a logical value indicating whether the eigenvalues of the matrix of the term $-\frac{1}{2}d_{ij}^2$ centred by rows and columns should be printed
<code>tol</code>	a tolerance threshold : an eigenvalue is considered positive if it is larger than $-\text{tol} \times \text{lambda1}$ where <code>lambda1</code> is the largest eigenvalue.

Value

returns a logical value indicating if all the eigenvalues are positive or equal to zero

Author(s)

Daniel Chessel
Stephane Dray <dray@biomserv.univ-lyon1.fr>

Examples

```
w <- matrix(runif(10000), 100, 100)
w <- dist(w)
summary(w)
IsEuclid (w) # TRUE
```

IsOdd

Checks If An Integer Is Even Or Odd

Description

Checks if the integers in a vector are even (FALSE) or odd (TRUE)

Usage

```
IsOdd(x)
```

Arguments

x vector of integers

Value

a logic vector

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[IsWhole](#)

Examples

```
IsOdd(1:10)
```

IsPrime

IsPrime Property

Description

Vectorized version, returning for a vector or matrix of positive integers a vector of the same size containing 1 for the elements that are prime and 0 otherwise.

Usage

```
IsPrime(x)
```

Arguments

x vector or matrix of nonnegative integers

Details

Given an array of positive integers returns an array of the same size of 0 and 1, where the i indicates a prime number in the same position.

Value

array of elements 0, 1 with 1 indicating prime numbers

Author(s)

Hans W. Borchers <hwborchers@googlemail.com>

See Also

[Factorize](#), [Primes](#)

Examples

```
x <- matrix(1:10, nrow=10, ncol=10, byrow=TRUE)
x * IsPrime(x)

# Find first prime number octett:
octett <- c(0, 2, 6, 8, 30, 32, 36, 38) - 19
while (TRUE) {
  octett <- octett + 210
  if (all(IsPrime(octett))) {
    cat(octett, "\n", sep=" ")
    break
  }
}
```

IsValidWrd

Check Word Pointer

Description

Check if a pointer points to a valid and running Word instance. The function does this by trying to get the current selection of the Word instance and returns FALSE if it's NULL.

Usage

```
IsValidWrd(wrd = getOption("lastWord"))
```

Arguments

wrd the pointer to a word instance as created by `GetNewWrd()` or `GetCurrWrd()`. Default is the last created pointer stored in `getOption("lastWord")`.

Value

logical value

Author(s)

Andri Signorell <andri@signorell.net>

[GetCurrWrd\(\)](#)

JarqueBeraTest *(Robust) Jarque Bera Test*

Description

This function performs the Jarque-Bera tests of normality either the robust or the classical way.

Usage

```
JarqueBeraTest(x, robust = TRUE, method = c("chisq", "mc"),
               N = 0, na.rm = FALSE)
```

Arguments

x	a numeric vector of data values.
robust	defines, whether the robust version should be used. Default is TRUE.
method	a character string out of chisq or mc, specifying how the critical values should be obtained. Default is approximated by the chisq-distribution or empirically via Monte Carlo.
N	number of Monte Carlo simulations for the empirical critical values
na.rm	defines if NAs should be omitted. Default is FALSE.

Details

The test is based on a joint statistic using skewness and kurtosis coefficients. The robust Jarque-Bera (RJB) version of utilizes the robust standard deviation (namely the mean absolute deviation from the Median ([MeanAD](#)) to estimate sample kurtosis and skewness. For more details see Gel and Gastwirth (2006).

Users can also choose to perform the classical Jarque-Bera test (see Jarque, C. and Bera, A (1980)).

Value

A list with class htest containing the following components:

statistic	the value of the test statistic.
parameter	the degrees of freedom.
p.value	the p-value of the test.
method	type of test was performed.
data.name	a character string giving the name of the data.

Note

This function is melted from the `jarque.bera.test` (in `tseries` package) and the `rjb.test` from the package `lawstat`.

x <- runif(100)     # alternative hypothesis
JarqueBeraTest(x, robust=TRUE)
```

JonckheereTerpstraTest

Exact Version of Jonckheere-Terpstra Test

Description

Jonckheere-Terpstra test to test for ordered differences among classes.

Usage

```
JonckheereTerpstraTest(x, ...)

## Default S3 method:
JonckheereTerpstraTest(x, g, alternative = c("two.sided", "increasing", "decreasing"),
  nperm = NULL, ...)

## S3 method for class 'formula'
JonckheereTerpstraTest(formula, data, subset, na.action, ...)
```

Arguments

x	a numeric vector of data values, or a list of numeric data vectors.
g	a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.
alternative	means are monotonic (two.sided), increasing, or decreasing

nperm	number of permutations for the reference distribution. The default is NULL in which case the permutation p-value is not computed. It's recommended to set nperm to 1000 or higher if permutation p-value is desired.
formula	a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
data	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula formula. By default the variables are taken from <code>environment(formula)</code> .
subset	an optional vector specifying a subset of observations to be used.
na.action	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
...	further argument to be passed to methods.

Details

JonckheereTerpstraTest is the exact (permutation) version of the Jonckheere-Terpstra test. It uses the statistic

$$\sum_{k < l} \sum_{ij} I(X_{ik} < X_{jl}) + 0.5I(X_{ik} = X_{jl}),$$

where i, j are observations in groups k and l respectively. The asymptotic version is equivalent to `cor.test(x, g, method="k")`. The exact calculation requires that there be no ties and that the sample size is less than 100. When data are tied and sample size is at most 100 permutation p-value is returned.

If x is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use `JonckheereTerpstraTest(x)` to perform the test. If the samples are not yet contained in a list, use `JonckheereTerpstraTest(list(x, ...))`.

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x .

Note

The function was previously published as `jonckheere.test()` in the **clinfun** package and has been integrated here without logical changes. Some argument checks and a formula interface were added.

Author(s)

  time=c(
    447,396,383,410,
    438,521,468,391,504,472,
    513,543,506,489,407),
  grp=Untable(c(4,6,5), type="ordered")[,1]
)

# the formula interface:
JonckheereTerpstraTest(time ~ grp, data=coffee)

```

KappaM

*Kappa for m raters***Description**

Computes kappa as an index of interrater agreement between m raters on categorical data.

Usage

```
KappaM(x, method = c("Fleiss", "Conger", "Light"), conf.level = NA)
```

Arguments

x	$n \times m$ matrix or dataframe, n subjects m raters.
method	a logical indicating whether the exact Kappa (Conger, 1980), the Kappa described by Fleiss (1971) or Light's Kappa (1971) should be computed.
conf.level	confidence level of the interval. If set to NA (which is the default) no confidence intervals will be calculated.

Details

Missing data are omitted in a listwise way.

The coefficient described by Fleiss (1971) does not reduce to Cohen's Kappa (unweighted) for m=2 raters. Therefore, the exact Kappa coefficient, which is slightly higher in most cases, was proposed by Conger (1980).

Light's Kappa equals the average of all possible combinations of bivariate Kappas between raters. The confidence levels can only be reported using Fleiss' formulation of Kappa.

Value

a single numeric value if no confidence intervals are requested,
and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

Note

This function was previously published as `kappam.fleiss()` in the **irr** package and has been integrated here with some changes in the interface.

KendallTauB

*Kendall tau-b***Description**

Calculate Kendall's tau-b. The estimator could also be calculated with `cor(..., method="kendall")`. The calculation of confidence intervals however would not be found there.

Usage

```
KendallTauB(x, y = NULL, conf.level = NA, ...)
```

Arguments

<code>x</code>	a numeric vector, matrix or data.frame.
<code>y</code>	NULL (default) or a vector with compatible dimensions to <code>x</code> . If <code>y</code> is provided, <code>table(x, y, ...)</code> is calculated.
<code>conf.level</code>	confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
<code>...</code>	further arguments are passed to the function <code>table</code> , allowing i.e. to set <code>useNA</code> . This refers only to the vector interface.

Value

a single numeric value if no confidence intervals are requested,
and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

KendallTauB(tab, conf.level=0.95)
```

KendallW

*Kendall's Coefficient of Concordance W***Description**

Computes Kendall's coefficient of concordance as an index of interrater reliability of ordinal data. The coefficient could be corrected for ties within raters.

Usage

```
KendallW(ratings, correct = FALSE, test = FALSE, na.rm = FALSE)
```

Arguments

ratings	$n \times m$ matrix or dataframe, k subjects (in rows) m raters (in columns).
correct	a logical indicating whether the coefficient should be corrected for ties within raters.
test	a logical indicating whether the test statistic and p-value should be reported.
na.rm	logical, indicating whether NA values should be stripped before the computation proceeds. If set to TRUE only the complete cases of the ratings will be used. Defaults to FALSE.

Details

Kendall's W should be corrected for ties, if raters did not use a true ranking order for the subjects. The test for the significance of Kendall's W is only valid for large samples.

Value

Either a single value if test is set to FALSE or else

a list with class "htest" containing the following components:

statistic	the value of the chi-square statistic.
p.value	the p-value for the test.
method	the character string "Kendall's coefficient of concordance W".
data.name	a character string giving the name(s) of the data.
estimate	the coefficient of concordance.
parameter	the degrees of freedom df, the number of subjects examined and the number of raters.

Note

This function was previously published as `kendall()` in the **irr** package and has been integrated here without logical changes, but with some adaptations in the result structure.

## Show Keywords associated with the 'merge' function
Keywords(merge)
Keywords("merge")
```

KrippAlpha

*Krippendorff's Alpha Reliability Coefficient***Description**

Calculate the alpha coefficient of reliability proposed by Krippendorff.

Usage

```
KrippAlpha(x, method=c("nominal", "ordinal", "interval", "ratio"))
```

Arguments

x	classifier x object matrix of classifications or scores
method	data level of x

Value

A list with class `"irrlist"` containing the following components:

method	a character string describing the method.
subjects	the number of data objects.
raters	the number of raters.
irr.name	a character string specifying the name of the coefficient.
value	value of alpha.
stat.name	here "nil" as there is no test statistic.
statistic	the value of the test statistic (NULL).
p.value	the probability of the test statistic (NULL).
cm	the concordance/discordance matrix used in the calculation of alpha
data.values	a character vector of the unique data values
levx	the unique values of the ratings
nmatchval	the count of matches, used in calculation
data.level	the data level of the ratings ("nominal", "ordinal", "interval", "ratio")

Note

Krippendorff's alpha coefficient is particularly useful where the level of measurement of classification data is higher than nominal or ordinal.

Note

This function was previously published as `kripp.alpha()` in the **irr** package and has been integrated here without logical changes, but with some adaptations in the result structure.

# now use the same data with the other three methods
KrippAlpha(nmm, "ordinal")
KrippAlpha(nmm, "interval")
KrippAlpha(nmm, "ratio")
```

Label	<i>Label Attribute of an Object</i>
-------	-------------------------------------

Description

Set and retrieve the label attribute of `x`. This can be helpful for documenting the specific meaning of a variable.

Usage

```
Label(x, default = NULL, ...)

## Default S3 method:
Label(x, ...)

## S3 method for class 'data.frame'
Label(x, ...)

Label(x, ...) <- value
```

```
## Default S3 replacement method:
Label(x, ...) <- value

## S3 replacement method for class 'data.frame'
Label(x, self = TRUE, ...) <- value
```

Arguments

x	any object
default	any default
value	any object
self	any object
...	the dots are passed to the specific function.

Details

The label should consist of a single text (length of 1). The text may contain any line feeds. It can be deleted by setting the label to NULL.

Value

Label returns the label attribute of x, if any; otherwise, NULL.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

A more elaborated version can be found in package **Hmisc** [label\(\)](#).

Examples

```
# add a descriptive label to a variable
Label(d.diamonds$colour) <- "The rating scale applied to diamonds ranges from colorless
to yellow, as any other color is extremely rare."

# technically just appending the text as attribute to the variable
attributes(d.diamonds$colour)

# label is supported while describing data
Desc(d.diamonds$colour)

# The label can be deleted by setting it to NULL
Label(d.diamonds$colour) <- NULL
```

 Lambda

Goodman Kruskal Lambda

Description

Calculate symmetric and asymmetric Goodman Kruskal lambda and their confidence intervals. Lambda is a measure of proportional reduction in error in cross tabulation analysis. For any sample with a nominal independent variable and dependent variable (or ones that can be treated nominally), it indicates the extent to which the modal categories and frequencies for each value of the independent variable differ from the overall modal category and frequency, i.e. for all values of the independent variable together

Usage

```
Lambda(x, y = NULL, direction = c("symmetric", "row", "column"), conf.level = NA, ...)
```

Arguments

x	a numeric vector, a matrix or a table.
y	NULL (default) or a vector with compatible dimensions to x. If y is provided, <code>table(x, y, ...)</code> is calculated.
direction	type of lambda. Can be one out of "symmetric" (default), "row", "column" (abbreviations are allowed). If direction is set to "row" then Lambda(RIC) (column dependent) will be reported. See details.
conf.level	confidence level for the returned confidence interval, restricted to lie between 0 and 1.
...	further arguments are passed to the function table , allowing i.e. to set <code>useNA = c("no", "ifany", "always")</code> .

Details

Asymmetric lambda is interpreted as the probable improvement in predicting the column variable Y given knowledge of the row variable X.

The nondirectional lambda is the average of the two asymmetric lambdas, `Lambda(CIR)` and `Lambda(RIC)`. `Lambda` (asymmetric and symmetric) has a scale ranging from 0 to 1.

Data can be passed to the function either as matrix or data.frame in x, or as two numeric vectors x and y. In the latter case `table(x, y, ...)` is calculated. Thus NAs are handled the same way as [table](#) does. Note that tables are by default calculated **without** NAs (which breaks the package's law to in general not omit NAs silently). The specific argument `useNA` can be passed via the ... argument.

[PairApply](#) can be used to calculate pairwise lambdas.

Value

if no confidence intervals are requested: the estimate as numeric value

else a named numeric vector with 3 elements

lambda	estimate
lwr.ci	lower confidence interval
upr.ci	upper confidence interval

Author(s)

Andri Signorell <andri@signorell.net> based on code from Antti Arppe <antti.arppe@helsinki.fi>, Nanina Anderegg (confidence interval symmetric lambda)

Large

Kth Smallest/Largest Values

Description

This function returns the kth smallest, resp. largest values from a vector x.

Usage

```
Small(x, k = 5, unique = FALSE, na.rm = FALSE)
Large(x, k = 5, unique = FALSE, na.rm = FALSE)
```

Arguments

x	a numeric vector
k	an integer >0 defining how many extreme values should be returned. Default is k = 5. If k > length(x), all values will be returned.
unique	logical, defining if unique values should be considered or not. If this is set to TRUE, a list with the k extreme values and their frequencies is returned. Default is FALSE (as unique is a rather expensive function).
na.rm	logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.

Details

There are several points of this problem discussed out there. This implementation uses the function `sort(..., partial)`, which isn't the fastest solution, but a fairly fast one.

Value

either a vector with the k most extreme values, if `unique` is set to `FALSE` or a list, containing the k most extreme values and their respective frequency.

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
x <- sample(1:10, 1000, rep=TRUE)
Large(x, 3)
Large(x, k=3, unique=TRUE)

# works fine up to x ~ 1e6
x <- runif(1000000)
Small(x, 3, unique=TRUE)
Small(x, 3, unique=FALSE)
```

Lc

Lorenz Curve

Description

Lc computes the (empirical) ordinary and generalized Lorenz curve of a vector x. Desc calculates some key figures for a Lorenz curve and produces a quick description.

Usage

```
Lc(x, ...)
```

Default S3 method:

```
Lc(x, n = rep(1, length(x)), na.rm = FALSE, ...)
```

S3 method for class 'formula'

```
Lc(formula, data, subset, na.action, ...)
```

S3 method for class 'Lc'

```
plot(x, general = FALSE, lwd = 2, type = "l", xlab = "p", ylab = "L(p)",
      main = "Lorenz curve", las = 1, ...)
```

S3 method for class 'Lclist'

```
plot(x, col = 1, lwd = 2, lty = 1, main = "Lorenz curve",
      xlab = "p", ylab = "L(p)", ...)
```

```
## S3 method for class 'Lc'
Desc(x, main = NULL, p = c(0.8, 0.9, 0.95, 0.99),
      plotit = getOption("plotit", FALSE), ...)
```

Arguments

<code>x</code>	a vector containing non-negative elements.
<code>n</code>	a vector of frequencies, must be same length as <code>x</code> .
<code>na.rm</code>	logical. Should missing values be removed? Defaults to FALSE.
<code>general</code>	logical. If TRUE the empirical Lorenz curve will be plotted.
<code>col</code>	color of the curve
<code>lwd</code>	the linewidth of the curve
<code>lty</code>	the linetype of the curve
<code>type</code>	type of the plot, default is line ("l").
<code>xlab, ylab</code>	label of the x-, resp. y-axis.
<code>main</code>	main title of the plot.
<code>las</code>	las of the axis.
<code>p</code>	a numeric vector with percent points, at which the Lorenz curve will be calculated.
<code>plotit</code>	boolean. Should a plot be created? Default is FALSE.
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further argument to be passed to methods.

Details

`Lc(x)` computes the empirical ordinary Lorenz curve of `x` as well as the generalized Lorenz curve (= ordinary Lorenz curve * `mean(x)`). The result can be interpreted like this: `p`*100 percent have `L(p)`*100 percent of `x`.

If `n` is changed to anything but the default `x` is interpreted as a vector of class means and `n` as a vector of class frequencies: in this case `Lc` will compute the minimal Lorenz curve (= no inequality within each group).

Value

A list of class "Lc" with the following components:

<code>p</code>	vector of percentages
<code>L</code>	vector with values of the ordinary Lorenz curve
<code>L.general</code>	vector with values of the generalized Lorenz curve

Note

These functions were previously published as `Lc()` in the **ineq** package and have been integrated here without logical changes.

LehmacherTest

Lehmacher's Test for Marginal Homogeneity

Description

Performs Lehmacher's chi-squared test for marginal homogeneity in a symmetric two-dimensional contingency table.

Usage

```

LehmacherTest(x, y = NULL)

## S3 method for class 'mtest'
print(x, digits = 4L, ...)

```

Arguments

<code>x</code>	either a two-dimensional contingency table in matrix form, or a factor object.
<code>y</code>	a factor object; ignored if <code>x</code> is a matrix.
<code>digits</code>	a non-null value for <code>digits</code> specifies the minimum number of significant digits to be printed in values. See details in print.default .
<code>...</code>	further arguments to be passed to or from other methods. They are ignored in this function.

Details

The null is that the probabilities of being classified into cells $[i,j]$ and $[j,i]$ are the same.

If `x` is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both `x` and `y` must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factors, and the contingency table is computed from these.

Value

A list with class "mtest" containing the following components:

<code>statistic</code>	a vector with the value of the test statistics.
<code>parameter</code>	the degrees of freedom, which is always 1 in <code>LehmacherTest</code> .
<code>p.value</code>	a vector with the p-values of the single tests.
<code>p.value.corr</code>	a vector with the "hochberg" adjusted p-values of the single tests. (See p.adjust)
<code>method</code>	a character string indicating what type of test was performed.
<code>data.name</code>	a character string giving the name of the data.

LeveneTest

*Levene's Test for Homogeneity of Variance***Description**

Computes Levene's test for homogeneity of variance across groups.

Usage

```
LeveneTest(y, ...)

## S3 method for class 'formula'
LeveneTest(y, data, ...)
## S3 method for class 'lm'
LeveneTest(y, ...)
## Default S3 method:
LeveneTest(y, group, center=median, ...)
```

Arguments

y	response variable for the default method, or a lm or formula object. If y is a linear-model object or a formula, the variables on the right-hand-side of the model must all be factors and must be completely crossed.
group	factor defining groups.
center	The name of a function to compute the center of each group; mean gives the original Levene's test; the default, median, provides a more robust test (Brown-Forsythe-Test).
data	a data frame for evaluating the formula.
...	arguments to be passed down, e.g., data for the formula and lm methods; can also be used to pass arguments to the function given by center (e.g., center=mean and trim=0.1 specify the 10% trimmed mean).

Value

returns an object meant to be printed showing the results of the test.

Note

This function was previously published as `leveneTest()` in the library(car) and has been integrated here without logical changes.

LillieTest

Lilliefors (Kolmogorov-Smirnov) test for normality

Description

Performs the Lilliefors (Kolmogorov-Smirnov) test for the composite hypothesis of normality, see e.g. Thode (2002, Sec. 5.1.1).

Usage

```
LillieTest(x)
```

Arguments

x a numeric vector of data values, the number of which must be greater than 4. Missing values are allowed.

Details

The Lilliefors (Kolmogorov-Smirnov) test is an EDF omnibus test for the composite hypothesis of normality. The test statistic is the maximal absolute difference between empirical and hypothetical cumulative distribution function. It may be computed as $D = \max\{D^+, D^-\}$ with

$$D^+ = \max_{i=1,\dots,n} \{i/n - p_{(i)}\}, D^- = \max_{i=1,\dots,n} \{p_{(i)} - (i-1)/n\},$$

where $p_{(i)} = \Phi([x_{(i)} - \bar{x}]/s)$. Here, Φ is the cumulative distribution function of the standard normal distribution, and \bar{x} and s are mean and standard deviation of the data values. The p-value is computed from the Dallal-Wilkinson (1986) formula, which is claimed to be only reliable when the p-value is smaller than 0.1. If the Dallal-Wilkinson p-value turns out to be greater than 0.1, then the p-value is computed from the distribution of the modified statistic $Z = D(\sqrt{n} - 0.01 + 0.85/\sqrt{n})$, see Stephens (1974), the actual p-value formula being obtained by a simulation and approximation process.

Value

A list with class “htest” containing the following components:

statistic	the value of the Lilliefors (Kolmogorov-Smirnov) statistic.
p.value	the p-value for the test.
method	the character string “Lilliefors (Kolmogorov-Smirnov) normality test”.
data.name	a character string giving the name(s) of the data.

Note

The Lilliefors (Kolmogorov-Smirnov) test is the most famous EDF omnibus test for normality. Compared to the Anderson-Darling test and the Cramer-von Mises test it is known to perform worse. Although the test statistic obtained from `LillieTest(x)` is the same as that obtained from `ks.test(x, "pnorm", mean(x), sd(x))`, it is not correct to use the p-value from the latter for the composite hypothesis of normality (mean and variance unknown), since the distribution of the test statistic is different when the parameters are estimated.

The function call `LillieTest(x)` essentially produces the same result as the S-PLUS function call `ks.gof(x)` with the distinction that the p-value is not set to 0.5 when the Dallal-Wilkinson approximation yields a p-value greater than 0.1. (Actually, the alternative p-value approximation is provided for the complete range of test statistic values, but is only used when the Dallal-Wilkinson approximation fails.)

```

lines.lm	<i>Add a Linear Regression Line</i>
----------	-------------------------------------

Description

Add a linear regression line to an existing plot. The function first calculates the prediction of a `lm` object for a reasonable amount of points, then adds the line to the plot and inserts a polygon with the confidence and prediction intervals.

Usage

```
## S3 method for class 'lm'
lines(x, col = getOption("col1", hblue), lwd = 2, lty = "solid",
      type = "l", n = 100, conf.level = 0.95, args.cband = NULL,
      pred.level = NA, args.pband = NULL, ...)
```

Arguments

<code>x</code>	linear model object as result from <code>lm(y~x)</code> .
<code>col</code>	linecolor of the line. Default is DescTools's lightblue.
<code>lwd</code>	line width of the line.
<code>lty</code>	line type of the line.
<code>type</code>	character indicating the type of plotting; actually any of the types as in plot.default . Type of plot, defaults to "l".
<code>n</code>	number of points used for plotting the fit.
<code>conf.level</code>	confidence level for the confidence interval. Set this to NA, if no confidence band should be plotted. Default is 0.95.
<code>args.cband</code>	list of arguments for the confidence band, such as color or border (see DrawBand).
<code>pred.level</code>	confidence level for the prediction interval. Set this to NA, if no prediction band should be plotted. Default is 0.95.
<code>args.pband</code>	list of arguments for the prediction band, such as color or border (see DrawBand).
<code>...</code>	further arguments are not used specifically.

Details

It's sometimes illuminating to plot a regression line with it's prediction, resp. confidence intervals over an existing xy-plot. This only makes sense, if just a simple regression model $y \sim x$ is to be visualized.

Value

nothing

Examples

```
par(mfrow=c(1,2))

plot(hp ~ wt, mtcars)
lines(lm(hp ~ wt, mtcars), col="steelblue")

# add the prediction intervals in different color
plot(hp ~ wt, mtcars)
r.lm <- lm(hp ~ wt, mtcars)
lines(r.lm, col="red", pred.level=0.95, args.pband=list(col=SetAlpha("grey",0.3)) )
```

lines.loess

Add a Loess or a Spline Smoother

Description

Add a loess smoother to an existing plot. The function first calculates the prediction of a loess object for a reasonable amount of points, then adds the line to the plot and inserts a polygon with the confidence intervals.

Usage

```
## S3 method for class 'loess'
lines(x, col = getOption("col1", hblue), lwd = 2, lty = "solid",
      type = "l", n = 100, conf.level = 0.95, args.band = NULL, ...)

## S3 method for class 'smooth.spline'
lines(x, col = getOption("col1", hblue), lwd = 2, lty = "solid",
      type = "l", conf.level = 0.95, args.band = NULL, ...)
```

Arguments

x	the loess or smooth.spline object to be plotted.
col	linecolor of the smoother. Default is DescTools's col1.
lwd	line width of the smoother.
lty	line type of the smoother.
type	type of plot, defaults to "l".
n	number of points used for plotting the fit.

<code>conf.level</code>	confidence level for the confidence interval. Set this to NA, if no confidence band should be plotted. Default is 0.95.
<code>args.band</code>	list of arguments for the confidence band, such as color or border (see DrawBand).
<code>...</code>	further arguments are passed to <code>loess()</code>

Note

Loess can result in heavy computational load if there are many points!

Author(s)

Andri Signorell <andri@signorell.net>

lines(loess(y~x))

plot(temperature ~ delivery_min, data=d.pizza)
lines(loess(temperature ~ delivery_min, data=d.pizza))

plot(temperature ~ delivery_min, data=d.pizza)
lines(loess(temperature ~ delivery_min, data=d.pizza), conf.level = 0.99,
      args.band = list(col=SetAlpha("red", 0.4), border="black") )

# the default values from scatter.smooth
lines(loess(temperature ~ delivery_min, data=d.pizza,
           span=2/3, degree=1, family="symmetric"), col="red")
```

LinScale

Perform a linear scaling of x

Description

This will scale the numeric vector `x` linearly from an old scale between `low` and `high` to a new one between `newlow` and `newhigh`.

Usage

```
LinScale(x, low = NULL, high = NULL, newlow = 0, newhigh = 1)
```

Arguments

<code>x</code>	a numeric matrix(like object).
<code>low</code>	numeric. The minimum value of the scale, defaults to <code>min(x)</code> . This is calculated columnwise by default; defined <code>low</code> or <code>high</code> arguments will be recycled if necessary.
<code>high</code>	numeric. The maximum value of the scale, defaults to <code>max(x)</code> . This is calculated columnwise by default; when a <code>maxval</code> is entered, it will be recycled.
<code>newlow</code>	numeric. The minimum value of the new scale, defaults to 0, resulting in a 0-1 scale for <code>x</code> . <code>newlow</code> is recycled if necessary.
<code>newhigh</code>	numeric. The maximum value of the scale, defaults to 1. <code>newhigh</code> is recycled if necessary.

Details

Hmm, hardly worth coding...

Value

The centered and scaled matrix. The numeric centering and scalings used (if any) are returned as attributes `"scaled:center"` and `"scaled:scale"`

```

LOCF*Last Observation Carried Forward*

Description

Replace NAs by the last observed value (aka "Last Observation Carried Forward").

Usage

```
LOCF(x)

## Default S3 method:
LOCF(x)
## S3 method for class 'data.frame'
LOCF(x)
## S3 method for class 'matrix'
LOCF(x)
```

Arguments

x a vector, a data.frame or a matrix containing NAs.

Details

The function will replace all NAs found in a vector with the last earlier value not being NA. In data.frames each column will be treated as described.

Value

a vector with the same dimension as x.

, val=rep(c(runif(5), rep(NA,2)), 4) )

d.frm$locf <- LOCF( d.frm$val )
d.frm
```

LOF*Local Outlier Factor*

Description

A function that finds the local outlier factor (Breunig et al.,2000) of the matrix "data" using k neighbours. The local outlier factor (LOF) is a measure of outlyingness that is calculated for each observation. The user decides whether or not an observation will be considered an outlier based on this measure. The LOF takes into consideration the density of the neighborhood around the observation to determine its outlyingness.

Usage

```
LOF(data, k)
```

Arguments

data	The data set to be explored
k	The kth-distance to be used to calculate the LOF's.

Details

The LOFs are calculated over a range of values, and the max local outlier factor is determined over this range.

Value

lof	A vector with the local outlier factor of each observation
-----	--

Note

This function was originally published in the library dprep.

Author(s)

Caroline Rodriguez

References

Examples

```
# Detecting the top 10 outliers using the LOF algorithm  
(iris.lof <- LOF(iris[,-5], 10))
```

Logit

*Generalized Logit and Inverse Logit function***Description**

Compute generalized logit and generalized inverse logit functions.

Usage

```
Logit(x, min = 0, max = 1)
LogitInv(x, min = 0, max = 1)
```

Arguments

x	value(s) to be transformed
min	lower end of logit interval
max	upper end of logit interval

Details

The generalized logit function takes values on [min, max] and transforms them to span [-Inf, Inf]. It is defined as:

$$y = \log \left(\frac{p}{1-p} \right) \quad \text{where} \quad p = \frac{x - \min}{\max - \min}$$

The generalized inverse logit function provides the inverse transformation:

$$x = p' \cdot (\max - \min) + \min \quad \text{where} \quad p' = \frac{\exp(y)}{1 + \exp(y)}$$

Value

Transformed value(s).

cbind(x, xt, y)
```

LogLin

*Log Linear Hybrid, Generalized Log***Description**

Computes the log linear hybrid transformation, resp. generalized log, with the goal to stabilize the variance.

Usage

```
LogLin(x, a)
LogGen(x, a)
```

Arguments

x a numeric vector, matrix or data frame.
a cutoff for the linear part of the transformation

Details

The log linear hybrid transformation function is linear for $x \leq a$ and logarithmic for $x > a$. It is continuously differentiable. The generalized log and log-linear hybrid transformations were introduced in then context of gene-expression microarray data by Rocke and Durbin (2003).

The function LogLin is currently defined as:

```
function (x, a) {
  x[x<=a] <- x[x<=a] / a + log(a) - 1
  x[x>a] <- log(x[x>a])
  return(x)
}
```

and LogGen as:

```
function (x, a) {
  return(log((x + sqrt(x^2 + a^2)) / 2))
}
```

Value

a numeric vector of the same dimensions as x containing the transformed results.

Author(s)

Andri Signorell <andri@signorell.net>

```

LogSt

*Started Logarithmic Transformation and Its Inverse***Description**

Transforms the data by a log10 transformation, modifying small and zero observations such that the transformation yields finite values.

Usage

```
LogSt(x, calib = x, threshold = NULL, mult = 1)
```

```
LogStInv(x, threshold = NULL)
```

Arguments

x	a vector or matrix of data, which is to be transformed
calib	a vector or matrix of data used to calibrate the transformation(s), i.e., to determine the constant c needed
threshold	constant c that determines the transformation. The inverse function will look for an attribute named "threshold" if the argument is set to NULL.
mult	a tuning constant affecting the transformation of small values, see Details

Details

Small values are determined by the threshold c. If not given by the argument threshold, then it is determined by the quartiles q1 and q3 of the non-zero data as those smaller than $c = q1 = (q3 - q1) \cdot \text{mult}$. The rationale is that for lognormal data, this constant identifies 2 percent of the data as small. Beyond this limit, the transformation continues linear with the derivative of the log curve at this point. See code for the formula.

Another possible value for the threshold c was: $\text{median}(x) / (\text{median}(x) / \text{quantile}(x, 0.25))^{2.9}$

The function chooses log10 rather than natural logs because they can be backtransformed relatively easily in the mind.

Value

the transformed data. The value c needed for the transformation is returned as `attr(,"threshold")`.

Note

The names of the function alludes to Tukey's idea of "started logs".

Examples

```
dd <- c(seq(0,1,0.1), 5 * 10^rnorm(100, 0, 0.2))
dd <- sort(dd)
r.dl <- LogSt(dd)
plot(dd, r.dl, type="l")
abline(v=attr(r.dl, "threshold"), lty=2)

x <- rchisq(df=3, n=100)
# should give 0 (or at least something small):
LogStInv(LogSt(x)) - x
```

LsFct

List Functions of a Package

Description

List all the functions of a package.

Usage

```
LsObj(package)
LsFct(package)
LsData(package)
```

Arguments

package the name of the package

Details

This is just a wrapper for [ls](#), [ls.str](#) and [lsf.str](#) with the appropriate arguments (as I always forgot how to do the trick). LsObj lists all objects, LsFct just the functions and LsData the data in an package (strictly speaking the lists).

Author(s)

Andri Signorell <andri@signorell.net>

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

LsFct("DescTools")
```

Mar

Set Plot Margins

Description

Plot margins are normally set by `par("mar")`. However one is forced to define all margins, even if just one should be altered. This convenience function allows to set one single margin (or several) while leaving the others unchanged.

Usage

```
Mar(bottom = NULL, left = NULL, top = NULL, right = NULL, outer = FALSE)
```

Arguments

bottom	the bottom margin, if set to NULL the current value will be maintained.
left	the left margin, if set to NULL the current value will be maintained.
top	the top margin, if set to NULL the current value will be maintained.
right	the right margin, if set to NULL the current value will be maintained.
outer	logical, defining if inner margins (<code>par("mar")</code>) or the outer margins (<code>par("oma")</code>) should be set. Default is FALSE, meaning that the inner margins will be concerned.

Author(s)

Andri Signorell <andri@signorell.net>

# enlarge the left margin only
Mar(,10.1)
barplot(1:7, names=levels(d.pizza$driver))
```

Mbind

Bind k $n \times m$ -matrices with the same dimension

Description

fable is nice to produce flat tables. But it does accept nothing but a n-dim table (resp. array) as argument.

So Mbind binds two (or n) $r \times c$ matrices to one 3-dimensional $n \times r \times c$ table(array), which can be passed to ftable to produce flat tables.

Usage

```
Mbind(...)
```

Arguments

... a list of 2 or more matrices of the same $n \times m$ Dimension.

Value

a 3dim array of the same class as the input matrices. If there are several classes, the matrices will be coerced following the usual R-rules.

names(dimnames(m1)) <- c("vname","area")

m2 <- do.call("rbind", lapply( d.pizza[,c("delivery_min","temperature")],
  tapply, d.pizza$area, median, na.rm=TRUE))
names(dimnames(m2)) <- c("vname","area")

m3 <- do.call("rbind", lapply( d.pizza[,c("delivery_min","temperature")],
  tapply, d.pizza$area, sd, na.rm=TRUE))
names(dimnames(m3)) <- c("vname","area")

m <- Mbind(mean=m1, median=m3, sd=m2)
m
class(m)

ftab <- round(ftable(m, col.vars=c("area")),2)
ftab

# two different classes
Mbind( alpha=matrix(letters[1:4], nrow=2), num=matrix(1:4, nrow=2))
```

```
# matrices with different dimensions are not allowed, following would raise an error:
# Mbind( matrix(letters[1:4], nrow=2), matrix(1:9, nrow=3))
```

MeanAD

Mean Absolute Deviation From a Center Point

Description

Calculates the mean absolute deviation from a center point, typically the sample mean or the median.

Usage

```
MeanAD(x, FUN = mean, na.rm = FALSE)
```

Arguments

x	a vector containing the observations.
FUN	the name of a function to be used as center. Can as well be a self defined function. Default is mean.
na.rm	a logical value indicating whether or not missing values should be removed. Defaults to FALSE.

Details

The MeanAD function calculates the mean absolute deviation from the mean value (or from another supplied center point) of x, after having removed NA values (if requested):

$$\frac{1}{n} \cdot \sum_{i=1}^n |x_i - c| \quad \text{where } c = \text{mean}(x) \text{ or } c = \text{med}(x)$$

It exists primarily to simplify the discussion of descriptive statistics during an introductory stats class.

Value

Numeric value.

Author(s)

Andri Signorell <andri@signorell.net> following an idea of Daniel Navarro (aad in the **lsr** package)

[mad](#)

Examples

```
x <- runif(100)
MeanAD(x)

speed <- c(58, 88, 40, 60, 72, 66, 80, 48, NA)
MeanAD(speed)
MeanAD(speed, na.rm=TRUE)

# using the median as centerpoint
x <- c(2,3,5,3,1,15,23)

MeanAD(x, FUN=mean)
MeanAD(x, FUN=median)

# define a fix center
MeanAD(x, 4)
```

MeanCI

*Confidence Interval for the Mean***Description**

Collection of several approaches to determine confidence intervals for the mean. Both, the classical way and bootstrap intervals are implemented for normal and trimmed means.

Usage

```
MeanCI(x, sd = NULL, trim = 0, method = c("classic", "boot"),
       conf.level = 0.95, na.rm = FALSE, ...)
```

Arguments

<code>x</code>	a (non-empty) numeric vector of data values.
<code>sd</code>	the standard deviation of <code>x</code> . If provided it's interpreted as sd of the population and the normal quantiles will be used for constructing the confidence intervals. If left to <code>NULL</code> (default) the sample <code>sd(x)</code> will be calculated and used in combination with the t-distribution.
<code>trim</code>	the fraction (0 to 0.5) of observations to be trimmed from each end of <code>x</code> before the mean is computed. Values of <code>trim</code> outside that range are taken as the nearest endpoint.
<code>method</code>	A vector of character strings representing the type of intervals required. The value should be any subset of the values "classic", "boot". See boot.ci .
<code>conf.level</code>	confidence level of the interval.
<code>na.rm</code>	a logical value indicating whether NA values should be stripped before the computation proceeds. Defaults to <code>FALSE</code> .
<code>...</code>	further arguments are passed to the boot function. Supported arguments are <code>type</code> ("norm", "basic", "stud", "perc", "bca"), <code>parallel</code> and the number of bootstrap replicates <code>R</code> . If not defined those will be set to their defaults, being "basic" for <code>type</code> , option "boot.parallel" (and if that is not set, "no") for <code>parallel</code> and 999 for <code>R</code> .

Details

The confidence intervals for the trimmed means use winsorized variances as described in the references.

Use [do.call](#), [rbind](#) and [lapply](#) for getting a matrix with estimates and confidence intervals for more than 1 column. (See examples!)

Value

a numeric vector with 3 elements:

mean	mean
lwr.ci	lower bound of the confidence interval
upr.ci	upper bound of the confidence interval

Author(s)

Andri Signorell <andri@signorell.net>

MeanCI(x, sd=25, na.rm=TRUE)

# the different types of bootstrap confints
MeanCI(x, method="boot", type="norm", na.rm=TRUE)
MeanCI(x, trim=0.1, method="boot", type="norm", na.rm=TRUE)
MeanCI(x, trim=0.1, method="boot", type="basic", na.rm=TRUE)
MeanCI(x, trim=0.1, method="boot", type="stud", na.rm=TRUE)
MeanCI(x, trim=0.1, method="boot", type="perc", na.rm=TRUE)
MeanCI(x, trim=0.1, method="boot", type="bca", na.rm=TRUE)

MeanCI(x, trim=0.1, method="boot", type="bca", R=1999, na.rm=TRUE)

# Getting the MeanCI for more than 1 column
round( do.call("rbind", lapply(d.pizza[,1:4], MeanCI, na.rm=TRUE)), 3)
```

MeanDiffCI

*Confidence Interval For Difference of Means***Description**

Calculates the confidence interval for the difference of two means either the classical way or with the bootstrap approach.

Usage

```
MeanDiffCI(x, ...)

## Default S3 method:
MeanDiffCI(x, y, method = c("classic", "norm", "basic", "stud", "perc", "bca"),
            conf.level = 0.95, na.rm = FALSE, R = 999, ...)

## S3 method for class 'formula'
MeanDiffCI(formula, data, subset, na.action, ...)
```

Arguments

<code>x</code>	a (non-empty) numeric vector of data values.
<code>y</code>	a (non-empty) numeric vector of data values.
<code>method</code>	a vector of character strings representing the type of intervals required. The value should be any subset of the values "classic", "norm", "basic", "stud", "perc", "bca". See boot.ci .
<code>conf.level</code>	confidence level of the interval.
<code>na.rm</code>	logical. Should missing values be removed? Defaults to FALSE.
<code>R</code>	the number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case <code>R</code> would be a vector of integers where each component gives the number of resamples from each of the rows of weights. See boot .
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further argument to be passed to or from methods.

Details

This function collects code from two sources. The classical confidence interval is calculated by means of [t.test](#). The bootstrap intervals are strongly based on the example in [boot](#).

Value

a numeric vector with 3 elements:

meandiff	the difference: mean(x) - mean(y)
lwr.ci	lower bound of the confidence interval
upr.ci	upper bound of the confidence interval

Author(s)

Andri Signorell <andri@signorell.net>

MeanDiffCI(x, y, method="bca", na.rm=TRUE)

# the formula interface
MeanDiffCI(price ~ driver, data=d.pizza, subset=driver %in% c("Carter","Miller"))
```

MeanSE	<i>Standard error of mean</i>
--------	-------------------------------

Description

Calculates the standard error of mean.

Usage

```
MeanSE(x, sd = NULL, na.rm = FALSE)
```

Arguments

x	a (non-empty) numeric vector of data values.
sd	the standard deviation of x. If provided it's interpreted as sd of the population. If left to NULL (default) the sample sd(x) will be used.
na.rm	logical. Should missing values be removed? Defaults to FALSE.

Details

MeanSE calculates the standard error of the mean defined as:

$$\frac{\sigma}{\sqrt{n}}$$

σ being standard deviation of x and n the length of x.

Value

the standard error as numeric value.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[MeanCI](#)

Examples

```
data(d.pizza)

MeanSE(d.pizza$price, na.rm=TRUE)

# evaluate data.frame
sapply(d.pizza[,1:4], MeanSE, na.rm=TRUE)
```

Measures of Shape *Skewness and Kurtosis*

Description

Skew computes the skewness, Kurt the kurtosis of the values in x.

Usage

```
Skew(x, na.rm = FALSE, method = 3, conf.level = NA, ci.type = "bca", R = 1000, ...)
```

```
Kurt(x, na.rm = FALSE, method = 3, conf.level = NA, ci.type = "bca", R = 1000, ...)
```

Arguments

x	a numeric vector. An object which is not a vector is coerced (if possible) by <code>as.vector</code> .
na.rm	logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.
method	integer out of 1, 2 or 3 (default). See Details.

<code>conf.level</code>	confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
<code>ci.type</code>	The type of confidence interval required. The value should be any subset of the values "classic", "norm", "basic", "stud", "perc" or "bca" ("all" which would compute all five types of intervals, is not supported).
<code>R</code>	The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case <code>R</code> would be a vector of integers where each component gives the number of resamples from each of the rows of weights.
<code>...</code>	the dots are passed to the function <code>boot</code> , when confidence intervals are calculated.

Details

If `na.rm` is TRUE then missing values are removed before computation proceeds.

The methods for calculating the skewness can either be:

```
method = 1:  g_1 = m_3 / m_2^(3/2)
method = 2:  G_1 = g_1 * sqrt(n(n-1)) / (n-2)
method = 3:  b_1 = m_3 / s^3 = g_1 ((n-1)/n)^(3/2)
```

and the ones for the kurtosis:

```
method = 1:  g_2 = m_4 / m_2^2 - 3
method = 2:  G_2 = ((n+1) g_2 + 6) * (n-1) / ((n-2)(n-3))
method = 3:  b_2 = m_4 / s^4 - 3 = (g_2 + 3) (1 - 1/n)^2 - 3
```

method = 1 is the typical definition used in many older textbooks.

method = 2 is used in SAS and SPSS.

method = 3 is used in MINITAB and BMDP.

Cramer et al. (1997) mention the asymptotic standard error of the skewness, resp. kurtosis:

```
ASE.skew = sqrt( 6n(n-1)/((n-2)(n+1)(n+3)) )
ASE.kurt = sqrt( (n^2 - 1)/((n-3)(n+5)) )
```

to be used for calculating the confidence intervals. This is implemented here with `ci.type="classic"`. However, Joanes and Gill (1998) advise against this approach, pointing out that the normal assumptions would virtually always be violated. They suggest using the bootstrap method. That's why the default method for the confidence interval type is set to "bca".

This implementation of the two functions is comparably fast, as the expensive sums are coded in C.

Value

If `conf.level` is set to NA then the result will be

a single numeric value

and if a `conf.level` is provided, a named numeric vector with 3 elements:

skew, kurt	the specific estimate, either skewness or kurtosis
lwr.ci	lower bound of the confidence interval
upr.ci	upper bound of the confidence interval

Author(s)

Andri Signorell <andri@signorell.net>, David Meyer <david.meyer@r-project.org> (method = 3)

```
Skew(d.pizza$price, na.rm=TRUE)
Kurt(d.pizza$price, na.rm=TRUE)

# use sapply to calculate skewness for a data.frame
sapply(d.pizza[,c("temperature", "price", "delivery_min")], Skew, na.rm=TRUE)

# or apply to do that columnwise with a matrix
apply(as.matrix(d.pizza[,c("temperature", "price", "delivery_min")]), 2, Skew, na.rm=TRUE)
```

median.factor

Median for Ordered Factors

Description

Calculate the median for ordered factors. This is not implemented in standard R, as it's not well defined (it is not clear what to do if the median sits between two levels in factors of even length). This function returns the high median and prints a warning if the low median would be different (which is supposed to be a rare event).

Usage

```
## S3 method for class 'factor'
median(x, na.rm = FALSE)
```

Arguments

x	an ordered factor containing the values whose median is to be computed.
na.rm	a logical value indicating whether NA values should be stripped before the computation proceeds.

Details

There's a vivid discussion between experts going on whether this should be defined or not. We'll wait for definitive results and enjoy the function's comfort so far...

Value

a level of the ordered factor.

Author(s)

Andri Signorell <andri@signorell.net>, based on code from Hong Ooi

Examples

```
median(d.pizza$quality, na.rm=TRUE)
```

MedianCI	<i>Confidence Interval for the Median</i>
----------	---

Description

Calculates the confidence interval for the median.

Usage

```
MedianCI(x, conf.level = 0.95, na.rm = FALSE,
         method = c("exact", "boot"), R = 999)
```

Arguments

x	a (non-empty) numeric vector of data values.
conf.level	confidence level of the interval
na.rm	logical. Should missing values be removed? Defaults to FALSE.
method	defining the type of interval that should be calculated (one out of "exact", "boot"). Default is "exact". See Details.
R	The number of bootstrap replicates. Usually this will be a single positive integer. See boot.ci for details.

Details

The exact method is the way SAS is said to calculate the confidence interval. This is implemented in [SignTest](#) and is extracted from there. The boot confidence interval type is calculated by means of [boot.ci](#) with default type "basic".

Use [sapply](#), resp. [apply](#), to get the confidence intervals from a data.frame or from a matrix.

Value

a numeric vector with 3 elements:

median	median
lwr.ci	lower bound of the confidence interval
upr.ci	upper bound of the confidence interval

Author(s)

Andri Signorell <andri@signorell.net>

MedianCI(d.pizza$price, na.rm=TRUE, method="exact")
MedianCI(d.pizza$price, na.rm=TRUE, method="boot")
```

MHChisqTest	<i>Mantel-Haenszel Chi-Square Test</i>
-------------	--

Description

The Mantel-Haenszel chi-square statistic tests the alternative hypothesis that there is a linear association between the row variable and the column variable. Both variables must lie on an ordinal scale.

Usage

```
MHChisqTest(x, srow = 1:nrow(x), scol = 1:ncol(x))
```

Arguments

x	a frequency table or a matrix.
srow	scores for the row variable, defaults to 1:nrow.
scol	scores for the column variable, defaults to 1:ncol.

Details

The statistic is computed as $Q_{MH} = (n - 1) \cdot r^2$, where r^2 is the Pearson correlation between the row variable and the column variable. The Mantel-Haenszel chi-square statistic use the scores specified by srow and scol. Under the null hypothesis of no association, Q_{MH} has an asymptotic chi-square distribution with one degree of freedom.

Value

A list with class "htest" containing the following components:

statistic	the value the Mantel-Haenszel chi-squared test statistic.
parameter	the degrees of freedom of the approximate chi-squared distribution of the test statistic.
p.value	the p-value for the test.
method	a character string indicating the type of test performed.
data.name	a character string giving the name(s) of the data.

Author(s)

Andri Signorell <andri@signorell.net>

References

Examples

```
## A r x c table Agresti (2002, p. 57) Job Satisfaction
Job <- matrix(c(1,2,1,0, 3,3,6,1, 10,10,14,9, 6,7,12,11), 4, 4,
              dimnames = list(income = c("< 15k", "15-25k", "25-40k", "> 40k"),
                              satisfaction = c("VeryD", "LittleD", "ModerateS", "VeryS")))
)

MHChisqTest(Job, srow=c(7.5,20,32.5,60))
```

Midx

Find the Midpoints of a Numeric Vector

Description

Calculate the midpoints of a sequence of numbers. This is e.g. useful for labelling stacked barplots.

Usage

```
Midx(x, incl.zero = FALSE, cumulate = FALSE)
```

Arguments

x	the numeric vector
incl.zero	should zero be appended to x before proceeding? If TRUE the first value will be one half of the first value of x. Default is FALSE.
cumulate	should the result be calculated as cumulative sum? Default is FALSE.

Value

numeric vector with the calculated midpoints

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
x <- c(1, 3, 6, 7)

Midx(x)
Midx(x, incl.zero = TRUE)
Midx(x, incl.zero = TRUE, cumulate = TRUE)

tab <- matrix(c(401,216,221,254,259,169), nrow=2, byrow=TRUE)
b <- barplot(tab, beside = FALSE, horiz=TRUE)

x <- t(apply(tab, 2, Midx, incl.zero=TRUE, cumulate=TRUE))
text(tab, x=x, y=b, col="red")
```

MixColor

Compute the convex combination of two colors

Description

This function can be used to compute the result of color mixing (it assumes additive mixing).

Usage

```
MixColor(col1, col2, amount1 = 0.5)
```

Arguments

col1	the first color.
col2	the second color.
amount1	the amount of color1. The amount of color2 results in (1-amount1).

Value

The mixed color as hexstring

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[colorRamp](#), [rgb](#)

Examples

```
# a mix between red and yellow with rates 3:7
MixColor("red", "yellow", 0.3)
```

Mode	<i>Mode</i>
------	-------------

Description

Calculates the mode, the most frequent value, of a variable *x*. This makes mostly sense for qualitative data.

Usage

```
Mode(x, na.rm = FALSE)
```

Arguments

<i>x</i>	a (non-empty) numeric vector of data values.
<i>na.rm</i>	logical. Should missing values be removed? Defaults to FALSE.

Value

Returns the most frequent value. If there are more than one, all of them are returned in a vector.

Note

Consider using `density(x)$x[which.max(density(x)$y)]` for quantitative data or alternatively use `hist()`.

Another interesting idea:

```
peak <- optimize(function(x, model) predict(model, data.frame(x = x)),
                  c(min(x), max(x)),
                  maximum = TRUE,
                  model = y.loess)
```

```
points(peak$maximum, peak$objective, pch=FILLED.CIRCLE <- 19)
```

Author(s)

Andri Signorell <andri@signorell.net>

See Also

data(d.pizza)
Mode(d.pizza$driver)
```

```
# use sapply for evaluating data.frames (resp. apply for matrices)
sapply(d.pizza[,c("driver", "temperature", "date")], Mode, na.rm=TRUE)
```

MosesTest

Moses Test of Extreme Reactions

Description

Perform Moses test of extreme reactions, which can be used to determine the difference in range between two samples. The exact one-tailed probability is calculated.

Usage

```
MosesTest(x, ...)

## Default S3 method:
MosesTest(x, y, extreme = NULL, ...)

## S3 method for class 'formula'
MosesTest(formula, data, subset, na.action, ...)
```

Arguments

x	numeric vector of data values. x will be treated as control group. Non-finite (e.g. infinite or missing) values will be omitted.
y	numeric vector of data values. y will be treated as experiment group. Non-finite (e.g. infinite or missing) values will be omitted.
formula	a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
data	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from <code>environment(formula)</code> .
subset	an optional vector specifying a subset of observations to be used.
na.action	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
extreme	integer, defines the number of extreme values to be dropped from the control group before calculating the span. Default (NULL) is the integer part of $0.05 * \text{length}(x)$ or 1, whichever is greater. If extreme is too large, it will be cut down to $\text{floor}(\text{length}(x)-2)/2$.
...	further arguments to be passed to or from methods.

Details

For two independent samples from a continuous field, this tests whether extreme values are equally likely in both populations or if they are more likely to occur in the population from which the sample with the larger range was drawn.

Note that the ranks are calculated in decreasing mode.

Value

A list with class “htest” containing the following components:

statistic	the value of the Moses Test statistic.
p.value	the p-value for the test.
method	the character string “Moses Test of Extreme Reactions”.
data.name	a character string giving the name(s) of the data.

MoveAvg

Moving Average

Description

Compute a simple moving average (running mean).

Usage

```
MoveAvg(x, order, align = c("center", "left", "right"),
        endrule = c("NA", "keep", "constant"))
```

Arguments

<code>x</code>	univariate time series.
<code>order</code>	order of moving average.
<code>align</code>	specifies whether result should be centered (default), left-aligned or right-aligned.
<code>endrule</code>	character string indicating how the values at the beginning and the end (of the data) should be treated. "keep" keeps the first and last k_2 values at both ends, where k_2 is the half-bandwidth $k_2 = k \% 2$, i.e., $y[j] = x[j]$ for $j \in \{1, \dots, k_2; n - k_2 + 1, \dots, n\}$; "constant" fill the ends with first and last calculated value in output array ($\text{out}[1:k_2] = \text{out}[k_2+1]$) "NA" the default, leaves the values to NA, as they are returned by filter .

Details

The implementation is using the function `filter` to calculate the moving average.

Value

Returns a vector of the same size and same class as `x`.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

There's a faster implementation of running mean in the package **caTools** `runmean()` and a slower one in **forecast** `ma()`.

Examples

```
MoveAvg(AirPassengers, order=5)
```

MultinomCI

Confidence Intervals for Multinomial Proportions

Description

Confidence intervals for multinomial proportions are often approximated by single binomial confidence intervals, which might in practice often yield satisfying results, but is properly speaking not correct. This function calculates simultaneous confidence intervals for multinomial proportions either according to the method of Sison and Glaz or according to Goodman's method.

Usage

```
MultinomCI(x, conf.level = 0.95, method = c("sisonglaz", "cplus1", "goodman"))
```

Arguments

<code>x</code>	A vector of positive integers representing the number of occurrences of each class. The total number of samples equals the sum of such elements.
<code>conf.level</code>	confidence level, defaults to 0.95.
<code>method</code>	character string specifying which method to use; can be one out of "sisonglaz", "cplus1", "goodman". Method can be abbreviated. See details. Defaults to "sisonglaz".

Details

Given a vector of observations with the number of samples falling in each class of a multinomial distribution, builds the simultaneous confidence intervals for the multinomial probabilities according to the method proposed by Sison and Glaz (1995). The R code has been translated from the SAS code written by May and Johnson (2000).

Value

A matrix with 3 columns:

<code>est</code>	estimate
<code>lwr.ci</code>	lower bound of the confidence interval
<code>upr.ci</code>	upper bound of the confidence interval

The number of rows correspond to the dimension of `x`.

Examples

```
# Multinomial distribution with 3 classes, from which a sample of 79 elements
# were drawn: 23 of them belong to the first class, 12 to the
# second class and 44 to the third class. Punctual estimations
# of the probabilities from this sample would be 23/79, 12/79
# and 44/79 but we want to build 95% simultaneous confidence intervals
# for the true probabilities

MultinomCI(c(23, 12, 44), conf.level=0.95)

x <- c(35, 74, 22, 69)

MultinomCI(x, method="goodman")
MultinomCI(x, method="sisonglaz")
MultinomCI(x, method="cplus1")

# compare to
BinomCI(x, n=sum(x))
```

Ndec

Count Decimal Places of a Number

Description

Returns the number of decimal places in the vector *x*. *x* must be a character and contain formatted numbers.

Usage

```
Ndec(x)
Prec(x)
```

Arguments

x is a character vector containing formatted numbers

Details

The function is currently defined as:

```
Ndec <- function(x) {
  stopifnot(class(x)=="character")
  res <- rep(0, length(x))
  x <- gsub(pattern="[eE].+$$", rep="", x=x)
  res[grepl("\\.",x)] <- nchar( sub("^.+[.]", "", x) )[grepl("\\.",x)]
  return(res)
}
```

Value

an integer value.

Note

```

x <- c("0.0000", "0", "159.283", "1.45e+10", "1.4599E+10" )
Ndec(x)
Prec(as.numeric(x))
```

NemenyiTest

Nemenyi Test

Description

Performs Nemenyi's test of multiple comparisons.

Usage

```
NemenyiTest(x, ...)

## Default S3 method:
NemenyiTest(x, g, dist = c("tukey", "chisq"), out.list = TRUE, ...)

## S3 method for class 'formula'
NemenyiTest(formula, data, subset, na.action,
             dist = c("tukey", "chisq"), out.list = TRUE, ...)
```

Arguments

<code>x</code>	a numeric vector of data values, or a list of numeric data vectors.
<code>g</code>	a vector or factor object giving the group for the corresponding elements of <code>x</code> . Ignored if <code>x</code> is a list.
<code>dist</code>	the distribution used for the test. Can be "tukey" or "chisq" (default is "tukey").
<code>out.list</code>	logical, defining if the output should be organized in listform.

formula	a formula of the form $\text{lhs} \sim \text{rhs}$ where lhs gives the data values and rhs the corresponding groups.
data	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from <code>environment(formula)</code> .
subset	an optional vector specifying a subset of observations to be used.
na.action	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
...	further arguments to be passed to or from methods.

Details

ToDo!! Tell when to use this test. References needed!

Value

A list of class `htest`, containing the following components:

statistic	Nemenyi test
p.value	the p-value for the test
null.value	is the value of the median specified by the null hypothesis. This equals the input argument <code>mu</code> .
alternative	a character string describing the alternative hypothesis.
method	the type of test applied
data.name	a character string giving the names of the data.

NemenyiTest(x~g, d.frm)
```

Description

Calculate the one period returns, the net present value (NPV) and internal rate of return (IRR) of a sequence of payments.

Usage

```
OPR(K, D = NULL, log = FALSE)
NPV(i, cf, t = seq(along = cf) - 1)
IRR(cf, t = seq(along = cf) - 1)
```

Arguments

i	the interest rate
cf	numeric vector with the payments
t	periods
K	the capital at time t

D	dividend at time t
log	logical, determining if the simple returns (default) or log returns are to be calculated.

Details

The one period returns are calculated as

$$r_t = \frac{D_t + K_t - K_{t-1}}{K_{t-1}}$$

Value

a numeric value

Author(s)

Andri Signorell <andri@signorell.net>

IRR(cf)
```

OddsRatio	<i>Odds Ratio Estimation and Confidence Intervals</i>
-----------	---

Description

Calculates odds ratio by unconditional maximum likelihood estimation (wald), conditional maximum likelihood estimation (mle) or median-unbiased estimation (midp). Confidence intervals are calculated using normal approximation (wald) and exact methods (midp, mle).

Usage

```
OddsRatio(x, y = NULL, conf.level = NA, method = c("wald", "mle", "midp"),
          interval = c(0, 1000), ...)
```

Arguments

x	a vector or a 2 × 2 numeric matrix, resp. table.
y	NULL (default) or a vector with compatible dimensions to x. If y is provided, table(x, y, ...) will be calculated.
method	method for calculating odds ratio and confidence intervals. Can be one out of "wald", "mle", "midp". Default is "wald" (not because it is the best, but because it is the most commonly used.)
conf.level	confidence level. Default is NA, meaning no confidence intervals will be reported.

interval interval for the function [uniroot](#) that finds the odds ratio median-unbiased estimate and midp exact confidence interval.

... further arguments are passed to the function [table](#), allowing i.e. to set useNA. This refers only to the vector interface.

Details

If a 2×2 table is provided the following table structure is preferred:

	disease=0	disease=1
exposed=0 (ref)	n00	n01
exposed=1	n10	n11

however, for odds ratios the following table is equivalent:

	disease=1	disease=0
exposed=1	n11	n10
exposed=0	n01	n00

If the table to be provided to this function is not in the preferred form, the function [Rev\(\)](#) can be used to "reverse" the table rows, resp. -columns. Reversing columns or rows (but not both) will lead to the inverse of the odds ratio.

In case of zero entries, 0.5 will be added to the table.

Value

a single numeric value if conf.level is set to NA
a numeric vector with 3 elements for estimate, lower and upper confidence interval if conf.level is provided

)

log(apply(migraine, 3, OddsRatio))
```

Outlier	<i>Outlier</i>
---------	----------------

Description

Return outliers following Tukey’s boxplot definition.

Usage

```
Outlier(x, method = c("boxplot"), na.rm = FALSE)
```

Arguments

- x a (non-empty) numeric vector of data values.
- method the method to be used. So far only Tukey’s boxplot rule is implemented.
- na.rm logical. Should missing values be removed? Defaults to FALSE.

Details

Outlier detection is a tricky problem and should be handled with care. We implement only Tukey’s boxplot rule as a rough idea of spotting extreme values.

Value

the values of x lying outside the whiskers in a boxplot

Author(s)

Andri Signorell <andri@signorell.net>

tapply(d.pizza$temperature, d.pizza$driver, Outlier, na.rm=TRUE)

# see also
boxplot(temperature ~ driver, d.pizza)$out
```

PageTest

Exact Page Test for Ordered Alternatives

Description

Performs a Page test for ordered alternatives using an exact algorithm by Stefan Wellek (1989) with unreplicated blocked data.

Usage

```
PageTest(y, ...)

## Default S3 method:
PageTest(y, groups, blocks, ...)

## S3 method for class 'formula'
PageTest(formula, data, subset, na.action, ...)
```

Arguments

y	either a numeric vector of data values, or a data matrix.
groups	a vector giving the group for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
blocks	a vector giving the block for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
formula	a formula of the form $a \sim b \mid c$, where a, b and c give the data values and corresponding groups and blocks, respectively.

<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

PageTest can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of groups and blocks) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of `y` is the same in each of the groups.

The implemented alternative is, that the location parameter will be monotonly greater along the groups,

$H_A : \theta_1 \leq \theta_2 \leq \theta_3 \dots$ (where at least one inequality is strict).

If the other direction is required, the order of the groups has to be reversed.

The Page test for ordered alternatives is slightly more powerful than the Friedman analysis of variance by ranks.

If `y` is a matrix, groups and blocks are obtained from the column and row indices, respectively. NA's are not allowed in groups or blocks; if `y` contains NA's, corresponding blocks are removed.

For small values of `k` (methods) or `N` (data objects), 'PageTest' will calculate the exact p-values. For '`k`, `N` > 15, `Inf`', a normal approximation is returned. Only one of these values will be returned.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	the L-statistic with names attribute "L".
<code>p.value</code>	the p-value of the test.
<code>method</code>	the character string "Page test for ordered alternatives".
<code>data.name</code>	a character string giving the names of the data.

Note

Special thanks to Prof. S. Wellek for porting old GAUSS code to R.

PairApply

Pairwise Calculations

Description

Implements a logic to run pairwise calculations on the columns of a data.frame or a matrix.

Usage

```
PairApply(x, FUN = NULL, ..., symmetric = FALSE)
```

Arguments

<code>x</code>	a list, a data.frame or a matrix with columns to be processed pairwise.
<code>FUN</code>	a function to be calculated. It is assumed, that the first 2 arguments denominate <code>x</code> and <code>y</code> .
<code>...</code>	the dots are passed to <code>FUN</code> .
<code>symmetric</code>	logical. Does the function yield the same result for <code>FUN(x, y)</code> and <code>FUN(y, x)</code> ? If <code>TRUE</code> just the lower triangular matrix is calculated and transposed. Default is <code>FALSE</code> .

Details

This code is based on the logic of `cor()` and extended for asymmetric functions.

Value

a matrix with the results of `FUN`.

Author(s)

Andri Signorell <andri@signorell.net>

Lambda(x=d.diamonds$colour, y=d.diamonds$clarity, direction="column")

# the data.frame
dfrm <- d.diamonds[, c("colour","clarity","cut","polish")]
PairApply(dfrm, FUN = CramerV, symmetric=TRUE)

# the same as matrix (columnwise)
m <- as.matrix(dfrm)
PairApply(m, FUN = CramerV, symmetric=TRUE)

# ... and the list interface
lst <- as.list(dfrm)
PairApply(lst, FUN = CramerV, symmetric=TRUE)
```

ParseFormula

Parse a Formula and Create a Model Frame

Description

Create a model frame for a formula object, by handling the left hand side the same way the right hand side is handled in model.frame. Especially variables separated by + are interpreted as separate variables.

Usage

```
ParseFormula(formula, data = parent.frame(), drop = TRUE)
```

Arguments

formula	an object of class "formula" (or one that can be coerced to that class): a symbolic description for the variables to be described.
data	an optional data frame, list or environment (or object coercible by <code>as.data.frame</code> to a data frame) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>lm</code> is called.
drop	if <code>drop</code> is TRUE, unused factor levels are dropped from the result when creating interaction terms. The default is to drop all unused factor levels.

Details

This is used by `Desc.formula` for describing data by groups while remaining flexible for using `I(...)` constructions, functions or interaction terms.

Value

a list of 3 elements

formula	the formula which had to be parsed
lhs	a list of 3 elements: mf: data.frame, the model.frame of the left hand side of the formula mf.eval: data.frame, the evaluated model.frame of the left hand side of the formula vars: the names of the evaluated model.frame
rhs	a list of 3 elements: mf: data.frame, the model.frame of the right hand side of the formula mf.eval: data.frame, the evaluated model.frame of the right hand side of the formula vars: the names of the evaluated model.frame

ParseSASDatalines	<i>Parse a SAS Dataline Command</i>
-------------------	-------------------------------------

Description

A parser for simple SAS dataline command texts. A `data.frame` is being built with the column-names listed in the input section. The data object will be created in the given environment.

Usage

```
ParseSASDatalines(x, env = .GlobalEnv, overwrite = FALSE)
```

Arguments

<code>x</code>	the SAS text
<code>env</code>	environment in which the dataset should be created.
<code>overwrite</code>	logical. If set to <code>TRUE</code> , the function will silently overwrite a potentially existing object in <code>env</code> with the same name as declared in the SAS DATA section. If set to <code>FALSE</code> (default) an error will be raised if there already exists an object with the same name.

Details

The SAS function `DATA` is designed for quickly creating a dataset from scratch. The whole step normally consists out of the `DATA` part defining the name of the dataset, an `INPUT` line declaring the variables and a `DATALINES` command followed by the values.

The default delimiter used to separate the different variables is a space (thus each variable should be one word). The `$` after the variable name indicates that the variable preceding contain character values and not numeric values. Without specific instructions, SAS assumes that variables are numeric. The function will fail, if it encounters a character in the place of an expected numeric value. Each new row in datalines will create a corresponding unique row in the dataset. Notice that a `;` is not needed after every row, rather it is included at the end of the entire data step.

More complex command structures, i.e. other delimiters (`dlim`), in the `INPUT`-section are not (yet) supported.

Value

a `data.frame`

```

PartCor	<i>Find the Correlations for a Set x of Variables With Set y Removed</i>
---------	--

Description

A straightforward application of matrix algebra to remove the effect of the variables in the y set from the x set. Input may be either a data matrix or a correlation matrix. Variables in x and y are specified by location.

Usage

```
PartCor(m, x, y)
```

Arguments

- m a data or correlation matrix.
- x the variable numbers associated with the X set.
- y the variable numbers associated with the Y set.

Details

It is sometimes convenient to partial the effect of a number of variables (e.g., sex, age, education) out of the correlations of another set of variables. This could be done laboriously by finding the residuals of various multiple correlations, and then correlating these residuals. The matrix algebra alternative is to do it directly.

Value

The matrix of partial correlations.

# by correlation matrix m
m <- cor(cbind(abstr, coord, age))
PartCor(m, 1:2, 3)

# ... which would be the same as:
lm1 <- lm(abstr ~ age)
lm2 <- lm(coord ~ age)

cor(resid(lm1), resid(lm2))
```

PartitionBy

PartitionBy Evaluates a Function Groupwise

Description

Split the vector `x` into partitions and apply the function to each partition separately. Computation restarts for each partition.

The logic is the same as the OLAP functions in SQL, e.g. `SUM(x) OVER (PARTITION BY group)`.

Usage

```
PartitionBy(x, by, FUN, ...)
```

Arguments

<code>x</code>	an atomic object, typically a vector.
<code>by</code>	list of one or more factors, each of same length as <code>X</code> . The elements are coerced to factors by as.factor .
<code>FUN</code>	Function to apply for each factor level combination.
<code>...</code>	optional arguments to <code>FUN</code> : the Note section.

Details

This is more or less the same as the function `ave`, with the arguments organized a bit different.

Value

a vector with the same length as `x` containing the groupwise results of `FUN`.

Note

Optional arguments to `FUN` supplied by the `...` argument are not divided into cells. It is therefore inappropriate for `FUN` to expect additional arguments with the same length as `X`.

PearsonTest

Pearson chi-square test for normality

Description

Performs the Pearson chi-square test for the composite hypothesis of normality.

Usage

```
PearsonTest(x, n.classes = ceiling(2 * (n^(2/5))), adjust = TRUE)
```

Arguments

x	a numeric vector of data values. Missing values are allowed.
n.classes	The number of classes. The default is due to Moore (1986).
adjust	logical; if TRUE (default), the p-value is computed from a chi-square distribution with n.classes-3 degrees of freedom, otherwise from a chi-square distribution with n.classes-1 degrees of freedom.

Details

The Pearson test statistic is $P = \sum (C_i - E_i)^2 / E_i$, where C_i is the number of counted and E_i is the number of expected observations (under the hypothesis) in class i . The classes are build is such a way that they are equiprobable under the hypothesis of normality. The p-value is computed from a chi-square distribution with `n.classes-3` degrees of freedom if `adjust` is `TRUE` and from a chi-square distribution with `n.classes-1` degrees of freedom otherwise. In both cases this is not (!) the correct p-value, lying somewhere between the two, see also Moore (1986).

Value

A list with class “htest” containing the following components:

<code>statistic</code>	the value of the Pearson chi-square statistic.
<code>p.value</code>	the p-value for the test.
<code>method</code>	the character string “Pearson chi-square normality test”.
<code>data.name</code>	a character string giving the name(s) of the data.
<code>n.classes</code>	the number of classes used for the test.
<code>df</code>	the degress of freedom of the chi-square distribution used to compute the p-value.

Note

The Pearson chi-square test is usually not recommended for testing the composite hypothesis of normality due to its inferior power properties compared to other tests. It is common practice to compute the p-value from the chi-square distribution with `n.classes - 3` degrees of freedom, in order to adjust for the additional estimation of two parameters. (For the simple hypothesis of normality (mean and variance known) the test statistic is asymptotically chi-square distributed with `n.classes - 1` degrees of freedom.) This is, however, not correct as long as the parameters are estimated by `mean(x)` and `var(x)` (or `sd(x)`), as it is usually done, see Moore (1986) for details. Since the true p-value is somewhere between the two, it is suggested to run `PearsonTest` twice, with `adjust = TRUE` (default) and with `adjust = FALSE`. It is also suggested to slightly change the default number of classes, in order to see the effect on the p-value. Eventually, it is suggested not to rely upon the result of the test.

The function call `PearsonTest(x)` essentially produces the same result as the S-PLUS function call `chisq.gof((x-mean(x))/sqrt(var(x)), n.param.est=2)`.

PercTable	<i>Percentage Table</i>
-----------	-------------------------

Description

Prints a 2-way contingency table along with percentages, marginal, and conditional distributions. All the frequencies are nested into one single table.

Usage

```
## Default S3 method:
PercTable(x, y = NULL, ...)

## S3 method for class 'table'
PercTable(tab, row.vars = NULL, col.vars = 2, digits = 3, big.mark = "", pfmt = FALSE,
          freq = TRUE, rfrq = "100", expected = FALSE, residuals = FALSE,
          stdres = FALSE, margins = NULL, ...)

## S3 method for class 'formula'
PercTable(formula, data, subset, na.action, ...)

MarginTable(tab)
```

Arguments

x, y	objects which can be interpreted as factors (including character strings). x and y will be tabulated via <code>table(x, y)</code> . If x is a matrix, it will be coerced to a table via <code>as.table(x)</code> .
tab	a r x c-contingency table
row.vars	a vector of row variables (see Details).
col.vars	a vector of column variables (see Details).
digits	an integer defining with how many digits the percentages will be printed.
big.mark	character. If not empty used as mark between every 3 decimals before the decimal point.
pfmt	logical. If set to TRUE the relative frequencies' format will be xx.xxx %, with digits respected.
freq	boolean. Should absolute frequencies be included? Defaults to TRUE.
rfrq	a string with 3 characters, each of them being 1 or 0. The first position means total percentages, the second means row percentages and the third column percentages. "011" produces a table output with row and column percentages.
expected	the expected counts under the null hypothesis.
residuals	the Pearson residuals, $(\text{observed} - \text{expected}) / \sqrt{\text{expected}}$.

<code>stdres</code>	standardized residuals, $(\text{observed} - \text{expected}) / \sqrt{V}$, where V is the residual cell variance (for the case where x is a matrix, $n * p * (1 - p)$ otherwise).
<code>margins</code>	a vector, consisting out of 1 and/or 2. Defines the margin sums to be included. 1 stands for row margins, 2 for column margins, $c(1,2)$ for both. Default is NULL (none).
<code>formula</code>	a formula of the form $\text{lhs} \sim \text{rhs}$ where lhs will be tabled versus rhs (<code>table(lhs, rhs)</code>).
<code>data</code>	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	the dots are passed from <code>PercTable.default()</code> to the <code>PercTable.table()</code> .

Details

`PercTable` prints a 2-dimensional table. The absolute and relative frequencies are nested into one flat table by means of `ftable`. By means of `row.vars`, resp. `col.vars`, the structure of the table can be defined. `row.vars` can either be the names of the dimensions (included percentages are named "idx") or numbers (1:3, where 1 is the first dimension of the table, 2 the second and 3 the percentages).

Use `Sort()` if you want to have your table sorted by rows.

`MarginTable` returns a list containing all the margin tables of a n -dimensional table along all dimensions. It does not much more than [margin.table](#) besides add percentages and do the job for all the dimensions.

Value

Returns an object of class "ftable".

PercTable(tab=tab, col.vars=2)

PercTable(tab=tab, col.vars=2, margins=c(1,2))
PercTable(tab=tab, col.vars=2, margins=2)
PercTable(tab=tab, col.vars=2, margins=1)
PercTable(tab=tab, col.vars=2, margins=NULL)

PercTable(tab=tab, col.vars=2, rfrq="000")

# just the percentages without absolute values
PercTable(tab=tab, col.vars=2, rfrq="110", freq=FALSE)

# just the row percentages in percent format (pfmt = TRUE)
PercTable(tab, freq= FALSE, rfrq="010", pfmt=TRUE, digits=1)

# just the expected frequencies and the standard residuals
PercTable(tab=tab, rfrq="000", expected = TRUE, stdres = TRUE)

# rearrange output such that freq are inserted as columns instead of rows
PercTable(tab=tab, col.vars=c(3,2), rfrq="111")

# putting the cities in rows
PercTable(tab=tab, col.vars=c(3,1), rfrq="100", margins=c(1,2))

# formula interface with subset
PercTable(driver ~ area, data=d.pizza, subset=wine_delivered==0)

# sort the table by rows, order first column (Zurich), then third, then row.names (0)
PercTable(tab=Sort(tab, ord=c(1,3,0)))

# the vector interface
PercTable(x=d.pizza$driver, y=d.pizza$area)
PercTable(x=d.pizza$driver, y=d.pizza$area, margins=c(1,2), rfrq="000", useNA="ifany")

# one dimensional x falls back to the function Freq()
PercTable(x=d.pizza$driver)

# the margin tables
MarginTable(Titanic)

```

Description

Return the set of permutations for a given set of values. The values can be numeric values, characters or factors.

Usage

```
Permn(x, sort = FALSE)
```

Arguments

x a vector of numeric values or characters. Characters need not be unique.

sort logical, defining if the result set should be sorted. Default is FALSE.

Details

The vector *x* need not contain unique values. The permutations will automatically be filtered for unique sets, if the same element is given twice or more.

Value

a data.frame with all possible permutations of the values in *x*.

PlotACF

Combined Plot of a Time Series and its ACF and PACF

Description

Combined plot of a time Series and its autocorrelation and partial autocorrelation

Usage

```
PlotACF(series, lag.max = 10 * log10(length(series)), ...)
PlotGACF(series, lag.max = 10 * log10(length(series)), type = "cor", ylab = NULL, ...)
```

Arguments

series	univariate time series.
lag.max	integer. Defines the number of lags to be displayed. The default is $10 * \log_{10}(\text{length}(\text{series}))$.
type	character string giving the type of acf to be computed. Allowed values are "cor" (the default), "cov" or "part" for autocorrelation, covariance or partial correlation.
ylab	a title for the y axis: see title .
...	the dots are passed to the plot command.

Details

PlotACF plots a combination of the time series and its autocorrelation and partial autocorrelation. PlotGACF is used as subfunction to produce the acf- and pacf-plots.

PlotArea

Create an Area Plot

Description

Produce a stacked area plot, or add polygons to an existing plot.

Usage

```
## Default S3 method:
PlotArea(x, y = NULL, prop = FALSE, add = FALSE, xlab = NULL,
         ylab = NULL, col = NULL, frame.plot = FALSE, ...)
## S3 method for class 'formula'
PlotArea(formula, data, subset, na.action = NULL, ...)
```

Arguments

x	numeric vector of x values, or if y=NULL a numeric vector of y values. Can also be a 1-dimensional table (x values in names, y values in array), matrix or 2-dimensional table (x values in row names and y values in columns), a data frame (x values in first column and y values in subsequent columns), or a time-series object of class ts/mts.
y	numeric vector of y values, or a matrix containing y values in columns.
prop	whether data should be plotted as proportions, so stacked areas equal 1.

<code>add</code>	whether polygons should be added to an existing plot.
<code>xlab</code>	label for x axis.
<code>ylab</code>	label for y axis.
<code>col</code>	fill color of polygon(s). The default is a vector of gray colors.
<code>frame.plot</code>	a logical indicating whether a box should be drawn around the plot.
<code>formula</code>	a formula , such as $y \sim x$ or $\text{cbind}(y1, y2) \sim x$, specifying x and y values. A dot on the left-hand side, $\text{formula} = . \sim x$, means all variables except the one specified on the right-hand side.
<code>data</code>	a data frame (or list) from which the variables in formula should be taken.
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NA values. The default is to ignore missing values in the given variables.
<code>...</code>	further arguments are passed to <code>matplot</code> and <code>polygon</code> .

Value

Matrix of cumulative sums that was used for plotting.

PlotBag

PlotBag, a bivariate boxplot

Description

`compute.PlotBag()` computes an object describing a `PlotBag` of a bivariate data set. `plot.PlotBag()` plots a bagplot object. `PlotBag()` computes and plots a bagplot.

Usage

```

PlotBag(x, y, factor = 3, na.rm = FALSE, approx.limit = 300,
        show.outlier = TRUE, show.whiskers = TRUE,
        show.looppoints = TRUE, show.bagpoints = TRUE,
        show.loophull = TRUE, show.baghull = TRUE,
        create.plot = TRUE, add = FALSE, pch = 16, cex = 0.4,
        dkmethode = 2, precision = 1, verbose = FALSE,
        debug.plots = "no", col.loophull = "#aaccff",
        col.looppoints = "#3355ff", col.baghull = "#7799ff",
        col.bagpoints = "#000088", transparency = FALSE, ...
)
PlotBagPairs(dm, trim = 0.0, main, numeric.only = TRUE,
            factor = 3, approx.limit = 300, pch = 16,
            cex = 0.8, precision = 1, col.loophull = "#aaccff",
            col.looppoints = "#3355ff", col.baghull = "#7799ff",
            col.bagpoints = "#000088", ...)

compute.bagplot(x, y, factor = 3, na.rm = FALSE, approx.limit = 300,
               dkmethode = 2, precision = 1, verbose = FALSE, debug.plots = "no" )

## S3 method for class 'bagplot'
plot(x, show.outlier = TRUE, show.whiskers = TRUE,
     show.looppoints = TRUE, show.bagpoints = TRUE,
     show.loophull = TRUE, show.baghull = TRUE, add = FALSE,
     pch = 16, cex = .4, verbose = FALSE, col.loophull = "#aaccff",
     col.looppoints = "#3355ff", col.baghull = "#7799ff",
     col.bagpoints = "#000088", transparency = FALSE,...)

```

Arguments

<code>x</code>	<code>x</code> values of a data set; in PlotBag: an object of class PlotBag computed by <code>compute.PlotBag</code>
<code>y</code>	<code>y</code> values of the data set
<code>factor</code>	factor defining the loop
<code>na.rm</code>	if TRUE 'NA' values are removed otherwise exchanged by median
<code>approx.limit</code>	if the number of data points exceeds <code>approx.limit</code> a sample is used to compute some of the quantities; default: 300
<code>show.outlier</code>	if TRUE outlier are shown
<code>show.whiskers</code>	if TRUE whiskers are shown
<code>show.looppoints</code>	if TRUE loop points are plotted
<code>show.bagpoints</code>	if TRUE bag points are plotted
<code>show.loophull</code>	if TRUE the loop is plotted
<code>show.baghull</code>	if TRUE the bag is plotted
<code>create.plot</code>	if FALSE no plot is created
<code>add</code>	if TRUE the bagplot is added to an existing plot
<code>pch</code>	sets the plotting character
<code>cex</code>	sets characters size
<code>dkmethod</code>	1 or 2, there are two method of approximating the bag, method 1 is very rough (only based on observations)
<code>precision</code>	precision of approximation, default: 1
<code>verbose</code>	automatic commenting of calculations
<code>debug.plots</code>	if TRUE additional plots describing intermediate results are constructed
<code>col.loophull</code>	color of loop hull
<code>col.looppoints</code>	color of the points of the loop
<code>col.baghull</code>	color of bag hull
<code>col.bagpoints</code>	color of the points of the bag
<code>transparency</code>	see section details
<code>dm</code>	<code>x</code>
<code>trim</code>	<code>x</code>
<code>main</code>	<code>x</code>
<code>numeric.only</code>	<code>x</code>
<code>...</code>	additional graphical parameters

Details

A bagplot is a bivariate generalization of the well known boxplot. It has been proposed by Rousseeuw, Ruts, and Tukey. In the bivariate case the box of the boxplot changes to a convex polygon, the bag of bagplot. In the bag are 50 percent of all points. The fence separates points within the fence from points outside. It is computed by increasing the the bag. The loop is defined as the convex hull containing all points inside the fence. If all points are on a straight line you get a classical boxplot. `PlotBag()` plots bagplots that are very similar to the one described in Rousseeuw et al. Remarks:

The two dimensional median is approximated. For large data sets the error will be very small. On the other hand it is not very wise to make a (graphical) summary of e.g. 10 bivariate data points.

In case you want to plot multiple (overlapping) bagplots, you may want plots that are semi-transparent. For this you can use the transparency flag. If `transparency==TRUE` the alpha layer is set to '99' (hex). This causes the bagplots to appear semi-transparent, but ONLY if the output device is PDF and opened using: `pdf(file="filename.pdf", version="1.4")`. For this reason, the default is `transparency==FALSE`. This feature as well as the arguments to specify different colors has been proposed by Wouter Meuleman.

Value

`compute.bagplot` returns an object of class `bagplot` that could be plotted by `plot.bagplot()`. An object of the `bagplot` class is a list with the following elements: `center` is a two dimensional vector with the coordinates of the center. `hull.center` is a two column matrix, the rows are the coordinates of the corners of the center region. `hull.bag` and `hull.loop` contain the coordinates of the hull of the bag and the hull of the loop. `pxy.bag` shows you the coordinates of the points of the bag. `pxy.outer` is the two column matrix of the points that are within the fence. `pxy.outlier` represent the outliers. The vector `hdepths` shows the depths of data points. `is.one.dim` is TRUE if the data set is (nearly) one dimensional. The dimensionality is decided by analysing the result of `prcomp` which is stored in the element `prdata`. `xy` shows you the data that are used for the bagplot. In the case of very large data sets subsets of the data are used for constructing the bagplot. A data set is very large if there are more data points than `approx.limit`. `xydata` are the input data structured in a two column matrix.

Note

Version of bagplot: 10/2012

```

PlotBubble

Draw a Bubble Plot

Description

Draw a bubble plot, defined by a pair of coordinates x , y to place the bubbles, an area definition configuring the dimension and a color vector setting the color of the bubbles. The legitimation to define a new function instead of just using `plot(symbols(...))` is the automated calculation of the axis limits, ensuring that all bubbles will be fully visible.

Usage

```
PlotBubble(x, ...)
```

```
## Default S3 method:
```

```
PlotBubble(x, y, area, col, border = NA, na.rm = FALSE, inches = FALSE, ...)
```

```
## S3 method for class 'formula'
```

```
PlotBubble(formula, data = parent.frame(), ..., subset, ylab = varnames[response])
```

Arguments

<code>x</code> , <code>y</code>	the x and y co-ordinates for the centres of the bubbles. They can be specified in any way which is accepted by xy.coords .
<code>area</code>	a vector giving the area of the bubbles.
<code>col</code>	colors for the bubbles, passed to symbol .
<code>border</code>	the border color for the bubbles. Set NA if there should be no border at all. This is the default.
<code>na.rm</code>	logical, should NAs be omitted? Defaults to FALSE.
<code>inches</code>	TRUE, FALSE or a positive number. See 'Details'.

formula	a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
data	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used.
ylab	the y-label for the plot used in the formula interface.
...	the dots are passed to the plot function.

Details

Argument inches controls the sizes of the symbols. If TRUE (the default), the symbols are scaled so that the largest dimension of any symbol is one inch. If a positive number is given the symbols are scaled to make largest dimension this size in inches (so TRUE and 1 are equivalent). If inches is FALSE, the units are taken to be those of the appropriate axes. This behaviour is the same as in [symbols](#).

Note

A legend can be added with [BubbleLegend](#).

Examples

```
PlotBubble(x=d.pizza$delivery_min, y=d.pizza$temperature, area=d.pizza$price/40,
           xlab="delivery time", ylab="temperature",
           col=SetAlpha(as.numeric(d.pizza$area)+2, .5), border="darkgrey",
           na.rm=TRUE, main="Price-Bubbles", panel.first=grid())

BubbleLegend("bottomleft", frame=TRUE, cols=SetAlpha("steelblue",0.5), bg="green",
             radius = c(10, 5, 2)/2, labels=c(10, 5, 2), cex=0.8,
             cols.lbl=c("yellow", "red", "blue"), width=12)
```

Description

Plot a candlestick chart. This is used primarily to describe price movements of a security, derivative, or currency over time. Candlestick charts are a visual aid for decision making in stock, foreign exchange, commodity, and option trading.

Usage

```
PlotCandlestick(x, y, xlim = NULL, ylim = NULL,
               col = c("springgreen4", "firebrick"),
               border = NA, args.grid = NULL, ...)
```

Arguments

<code>x</code>	a numeric vector for the x-values. Usually a date.
<code>y</code>	the y-values in a matrix (or a data.frame that can be coerced to a matrix) with 4 columns, whereas the first column contains the open price, the second the high, the third the lowest and the 4th the close price of daily stock prices.
<code>xlim</code>	the x limits (x1, x2) of the plot. The default value, NULL, indicates that the range of the finite values to be plotted should be used.
<code>ylim</code>	the y limits of the plot.
<code>col</code>	color for the body. To better highlight price movements, modern candlestick charts often replace the black or white of the candlestick body with colors such as red for a lower closing and blue or green for a higher closing.
<code>border</code>	the border color of the rectangles. Default is NA, meaning no border will be plotted.
<code>args.grid</code>	the arguments of a potential grid. Default is NULL, which will have a grid plotted. If arguments are provided, they have to be organized as list with the names of the arguments. (For example: ..., args.grid = list(col="red"))
<code>...</code>	the dots are passed to plot() command

Details

Candlesticks are usually composed of the body (black or white), and an upper and a lower shadow (wick): the area between the open and the close is called the real body, price excursions above and below the real body are called shadows. The wick illustrates the highest and lowest traded prices of a security during the time interval represented. The body illustrates the opening and closing trades. If the security closed higher than it opened, the body is white or unfilled, with the opening price at the bottom of the body and the closing price at the top. If the security closed lower than it opened, the body is black, with the opening price at the top and the closing price at the bottom. A candlestick need not have either a body or a wick.

```

PlotCirc

Plot Circular Plot

Description

This visualising scheme represents the unidirectional relationship between the rows and the columns of a contingency table.

Usage

```

PlotCirc(tab, acol = rainbow(sum(dim(tab))), aborder = "darkgrey",
         rcol = SetAlpha(acol[1:nrow(tab)], 0.5), rborder = "darkgrey",
         gap = 5, main = "", labels = NULL, cex.lab = 1.0, las = 1,
         adj = NULL, dist = 2)

```

Arguments

tab	a table to be visualised.
acol	the colors for the peripheral annuli.
aborder	the border colors for the peripheral annuli.
rcol	the colors for the ribbons.
rborder	the border colors for the ribbons.
gap	the gap between the entities in degrees.
main	the main title, defaults to "".
labels	the labels. Defaults to the column names and rownames of the table.
las	alignment of the labels, 1 means horizontal, 2 radial and 3 vertical.
adj	adjustments for the labels. (Left: 0, Right: 1, Mid: 0.5)
dist	gives the distance of the labels from the outer circle. Default is 2.
cex.lab	the character extension for the labels.

Details

The visual scheme of representing relationships can be applied to a table, given the observation that a table cell is a relationship (with a value) between a row and column. By representing the row and columns as segments along the circle, the information in the corresponding cell can be encoded as a link between the segments. In general, the cell represents a unidirectional relationship (e.g. row->column) - in this relationship the role of the segments is not interchangeable (e.g. (row,col) and (col,row) are different cells). To identify the role of the segment, as a row or column, the ribbon is made to terminate at the row segment but slightly away from the column segment. In this way, for a given ribbon, it is easy to identify which segment is the row and which is the column.

Value

the calculated points for the labels, which can be used to place userdefined labels.

par(mfrow=c(1,2))
PlotCirc(tab, main="weekday ~ operator")
PlotCirc(t(tab), main="operator ~ weekday")
```

PlotCorr

Plot a Correlation Matrix

Description

This function produces a graphical display of a correlation matrix. The cells of the matrix can be shaded or colored to show the correlation value.

Usage

```
PlotCorr(x, cols = colorRampPalette(c(getOption("col1", hred), "white",
                                     getOption("col2", hblue)), space = "rgb")(20),
        breaks = seq(-1, 1, length = length(cols) + 1),
        border = "grey", lwd = 1,
        args.colorlegend = NULL, xaxt = par("xaxt"), yaxt = par("yaxt"),
        cex.axis = 0.8, las = 2, mar = c(3, 8, 8, 8), ...)
```

Arguments

<code>x</code>	<code>x</code> is a correlation matrix to be visualized.
<code>cols</code>	the colors for shading the matrix. Uses the package's option "col1" and "col2" as default.
<code>breaks</code>	a set of breakpoints for the colours: must give one more breakpoint than colour. These are passed to <code>image()</code> function. If <code>breaks</code> is specified then the algorithm used follows <code>cut</code> , so intervals are closed on the right and open on the left except for the lowest interval.
<code>border</code>	color for borders. The default is grey. Set this argument to NA if borders should be omitted.
<code>lwd</code>	line width for borders. Default is 1.
<code>args.colorlegend</code>	list of arguments for the ColorLegend . Use NA if no color legend should be painted.
<code>xaxt</code>	parameter to define, whether to draw an x-axis, defaults to "n".
<code>yaxt</code>	parameter to define, whether to draw an y-axis, defaults to "n".
<code>cex.axis</code>	character extension for the axis labels.
<code>las</code>	the style of axis labels.
<code>mar</code>	sets the margins, defaults to <code>mar = c(3, 8, 8, 8)</code> as we need a bit more room on the right.
<code>...</code>	the dots are passed to the function image , which produces the plot.

Value

no values returned.

PlotDesc

Display descriptive plots

Description

Specific descriptive plots depending on the class of x. These will typically be called by the Desc routines with the plotit argument set to TRUE.

Usage

```

PlotDesc(x, ..., wrd = NULL)

## Default S3 method:
PlotDesc(x, ...)

## S3 method for class 'integer'
PlotDesc(x, main = deparse(substitute(x)),
         ord = c("val_asc", "val_desc", "frq_asc", "frq_desc"),
         maxrows = 10, ..., wrd = NULL)

## S3 method for class 'numeric'
PlotDesc(x, main = deparse(substitute(x)), ...,
         wrd = NULL)

## S3 method for class 'factor'
PlotDesc(x, main = deparse(substitute(x)),
         ord = c("desc", "level", "name", "asc", "none"),
         maxrows = 10, lablen = 25, type = c("bar", "dot"),
         col = NULL, border = NULL, xlim=NULL, ecdf=FALSE, ..., wrd = NULL)

## S3 method for class 'table'
PlotDesc(x, col1 = getOption("col1", hblue),

```

```

        col2 = getOption("col2", hred),
        horiz = TRUE, main="", ..., wrd = NULL)
## S3 method for class 'matrix'
PlotDesc(x, col1 = getOption("col1", hblue),
        col2 = getOption("col2", hred),
        horiz = TRUE, main="", ..., wrd = NULL)

## S3 method for class 'ordered'
PlotDesc(x, ..., wrd = NULL)

## S3 method for class 'data.frame'
PlotDesc(x, ..., wrd = NULL)

## S3 method for class 'logical'
PlotDesc(x, main = deparse(substitute(x)), xlab = "",
        col1 = getOption("col1", hblue),
        col2 = getOption("col2", hred), ..., wrd = NULL)

## S3 method for class 'Date'
PlotDesc(x, main = deparse(substitute(x)), breaks = NULL, ..., wrd = NULL)

## S3 method for class 'flags'
PlotDesc(x, ..., wrd = NULL)

PlotDescNumFact(formula, data, main = deparse(formula), notch=FALSE,
        add_ni = TRUE, ..., wrd = NULL)

PlotDescFactNum(x, y, ptab,
        col1 = getOption("col1", hblue), col2 = getOption("col2", hred),
        main=NULL, notch=FALSE, add_ni = TRUE, ... , wrd=NULL)

PlotDescNumNum(form1, form2, data, main = NULL, xlab = NULL, ylab = NULL, ..., wrd = NULL)

```

Arguments

<code>x</code>	the vector to be plotted.
<code>main</code>	the main title of the plot.
<code>ord</code>	the row order of a frequency table to be chosen. Is used for factors and integers.
<code>maxrows</code>	the maximum number of rows to be displayed for a factor.
<code>lablen</code>	the maximum number of characters for a factor level to be displayed, before the level is truncated and ... are added.
<code>type</code>	the type of plot to be used for describing factors. Can be "bar" for a horizontal barchart or "dot" for a dotchart.
<code>col1, col2</code>	two colors to be chosen for doing mosaicplots and logic plots.
<code>col</code>	color of the points used in a dotchart, typically for integers. Defaults to lightblue.
<code>border</code>	the color of the border, if the plottype is barplot or dotplot
<code>xlab</code>	the label for the x-axis.
<code>ylab</code>	the label for the y-axis.
<code>xlim</code>	the limits of the x-axis in factor plots.

<code>ecdf</code>	logical, defining if cumulative frequencies should be displayed in <code>PlotDesc.factor</code> . Defaults to <code>FALSE</code> .
<code>breaks</code>	vector of limits to bin a date.
<code>horiz</code>	logical, indicating if the two mosaicplots should be arranged horizontally (default is <code>TRUE</code>).
<code>formula</code>	a formula, such as <code>y ~ grp</code> , where <code>y</code> is a numeric vector of data values to be split into groups according to the grouping variable <code>grp</code> (usually a factor).
<code>data</code>	a <code>data.frame</code> (or list) from which the variables in <code>formula</code> should be taken.
<code>notch</code>	if <code>notch</code> is <code>TRUE</code> , a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is 'strong evidence' that the two medians differ.
<code>add_ni</code>	logical. Indicates if the group length should be displayed in the boxplot.
<code>form1, form2</code>	the formula used for calculating the smoother.
<code>wrd</code>	the pointer to a word instance. Can be a new one, created by <code>GetNewWrd()</code> or an existing one, created by <code>GetCurrWrd()</code> . Default is the last created pointer stored in <code>getOption("lastWord")</code> .
<code>y</code>	the response variable
<code>ptab</code>	the proportions table for the deciles of <code>x</code> used in <code>PlotDesc.flags</code> .
<code>...</code>	further arguments

d.frm <- d.pizza[,c("price", "operator")]
d.frm <- d.frm[complete.cases(d.frm),]
PlotDescNumFact(temperature ~ driver, data=d.pizza) # numeric ~ factor

PlotDesc(table(d.pizza$driver, d.pizza$operator)) # factor ~ factor
```

Description

Draw a Cleveland dot plot. This is an extended version of [dotchart](#) with an added option for error bars and an add argument.

Usage

```
PlotDot(x, labels = NULL, groups = NULL, gdata = NULL,
        cex = par("cex"), pch = 21, gpch = 21, bg = par("bg"),
        color = par("fg"), gcolor = par("fg"), lcolor = "gray",
        xlim = NULL, main = NULL, xlab = NULL, ylab = NULL,
        add = FALSE, args.errbars = NULL, ...)
```

Arguments

x	either a vector or matrix of numeric values (NAs are allowed). If x is a matrix the overall plot consists of juxtaposed dotplots for each row. Inputs which satisfy is.numeric(x) but not is.vector(x) is.matrix(x) are coerced by as.numeric , with a warning.
labels	a vector of labels for each point. For vectors the default is to use names(x) and for matrices the row labels dimnames(x)[[1]] .
groups	an optional factor indicating how the elements of x are grouped. If x is a matrix, groups will default to the columns of x.
gdata	data values for the groups. This is typically a summary such as the median or mean of each group.
cex	the character size to be used. Setting cex to a value smaller than one can be a useful way of avoiding label overlap. Unlike many other graphics functions, this sets the actual size, not a multiple of par("cex") .
pch	the plotting character or symbol to be used.
gpch	the plotting character or symbol to be used for group values.
bg	the background color of plotting characters or symbols to be used; use par(bg= *) to set the background color of the whole plot.
color	the color(s) to be used for points and labels.
gcolor	the single color to be used for group labels and values.
lcolor	the color(s) to be used for the horizontal lines.
xlim	horizontal range for the plot, see plot.window , e.g.
main	overall title for the plot, see title .
xlab, ylab	axis annotations as in title .
add	logical specifying if bars should be added to an already existing plot; defaults to FALSE.
args.errbars	optional arguments for adding error bars. All arguments for ErrBars can be supplied. If left to NULL (default), no error bars will be plotted.
...	graphical parameters can also be specified as arguments.

Details

This function is invoked for its side effect, which is to produce two variants of dotplots as described in Cleveland (1985).

Dot plots are a reasonable substitute for bar plots.

Value

Return the y-values used for plotting.

Examples

```
PlotDot(VADeaths, main = "Death Rates in Virginia - 1940")
op <- par(xaxs = "i") # 0 -- 100%
PlotDot(t(VADeaths), xlim = c(0,100),
        main = "Death Rates in Virginia - 1940")
par(op)

# add some error bars
PlotDot(VADeaths, main="Death Rates in Virginia - 1940", col="red", pch=NA,
        args.errbars = list(from=VADeaths-2, to=VADeaths+2, mid=VADeaths,
                             pch=21, cex=1.4))

# add some other values
PlotDot(VADeaths+3, pch=15, col="blue", add=TRUE, labels=NA)

# same as PlotDotCI
xci <- do.call(rbind, tapply( d.pizza$delivery_min, d.pizza$driver,
                             MeanCI, conf.level=0.99, na.rm=TRUE))

PlotDot(xci[,1], main="delivery_min ~ driver",
        args.errbars = list(from=xci[,2], to=xci[,3], mid=xci[,1],
                             lwd=2, pch=21, col="grey40", bg.pch="grey50", col.pch="black"),
        xlim=c(15,35), panel.before=grid())

# with group data
x <- with(d.pizza, tapply(temperature, list(area, driver), mean, na.rm=TRUE))

PlotDot(x, gdata = tapply(d.pizza$temperature, d.pizza$driver, mean, na.rm=TRUE),
        gpch = 15)

# special format
par(lend=1)

PlotDot(VADeaths, main="Death Rates in Virginia - 1940", pch=NA, lcolor = hecru,
```

```
args.errbars = list(from=VADeaths-2, to=VADeaths+2, mid=VADeaths,
                    pch="|", col.pch=hred, cex=1.3, lwd=8, code=0, col=hgreen))
```

PlotDotCI

*Plot a Dotchart with Confidence Intervals***Description**

Plot a dotchart with confidence intervals as segments. The reason for creating a new function for the job is the automated calculation of the axis limits, ensuring all error bars will be fully visible.

Usage

```
PlotDotCI(x, xlim = NULL,
          pch = 21, pch.cex = 1, pch.col = "black", pch.bg = "grey50",
          lcol = "grey40", lwd = 2,
          args.legend = NULL, code = 3, lend = "butt",
          mar = c(7.1, 4.1, 4.1, 2.1), ...)
```

Arguments

x	matrix with 3 columns, the first is used as x-values, the second is the left bound and the 3rd the right bound of the segment.
xlim	the x limits of the plot.
pch	a vector of plotting characters or symbols.
pch.cex	magnification to be used for plotting characters relative to the current setting of cex.
pch.col	the colors for points. If using 21 etc. this is the margins color of the point character.
pch.bg	the colors for points. If using 21 etc. this is the fill color of the point character.
lcol	the colors for lines.
lwd	the widths for the segments.
lend	the line end style. This can be specified as an integer or string, 0: "round", 1: "butt", 2: "square"
args.legend	list of additional arguments to be passed to the legend function. Use args.legend = NA if no legend should be added.
code	integer value. Determines the kind of arrows to be drawn. code = 1 means that a lower arrowhead will be drawn, code = 2 will produce one on the right side and code = 3 on both sides. (See the function arrows).
mar	numeric vector with margins defined.
...	further arguments are passed to the function dotchart .

[PlotDotCIp](#)

Examples

```
xci <- do.call(rbind, tapply( d.pizza$delivery_min, d.pizza$driver,
  MeanCI, conf.level=0.99, na.rm=TRUE))

PlotDotCI(xci, main="delivery_min ~ driver",
  args.legend=list(y=-1.5, legend=c("estimate", "99%-CI")))
```

PlotDotCIp*Plot a Dotchart with Binomial Confidence Intervals*

Description

Plot a dotchart with binomial confidence intervals ("wilson") as segments.

Usage

```
PlotDotCIp(x, n, xlim = c(0, 1),
  ord = c("rel", "abs", "names"), decreasing = FALSE, ...)
```

Arguments

x	number of successes, or a vector of length 2 giving the numbers of successes and failures, respectively.
n	number of trials; ignored if x has length 2.
xlim	the x limits of the plot.
ord	how should the result be ordered? Default is relative frequency "rel". The argument can be abbreviated.
decreasing	logical, sort order decreasing or ascending?
...	further arguments are passed to the function PlotDotCI().

PlotDotCIp(x=tab[,2], n=apply(tab,1,sum), ord="abs", dec=TRUE)
```

PlotFaces

*Chernoff Faces***Description**

Plot Chernoff faces. The rows of a data matrix represent cases and the columns the variables.

Usage

```
PlotFaces(xy, which.row, fill = FALSE, nrow, ncol,
          scale = TRUE, byrow = FALSE, main, labels, print.info=FALSE, col=NA)
```

Arguments

xy	xy data matrix, rows represent individuals and columns attributes.
which.row	defines a permutation of the rows of the input matrix.
fill	logic. If set to TRUE, only the first nc attributes of the faces are transformed, nc is the number of columns of x.
nrow	number of columns of faces on graphics device
ncol	number of rows of faces
scale	logic. If set to TRUE, attributes will be normalized.
byrow	if (byrow==TRUE), x will be transposed.
main	title.
labels	character strings to use as names for the faces.
print.info	if TRUE information about usage of variables for face elements are printed.
col	a vector of colors used for the parts of the faces. Default is NA, which will omit colors.

Details

The features parameters of this implementation are:

- 1 height of face
- 2 width of face
- 3 shape of face
- 4 height of mouth
- 5 width of mouth
- 6 curve of smile
- 7 height of eyes
- 8 width of eyes
- 9 height of hair
- 10 width of hair
- 11 styling of hair
- 12 height of nose
- 13 width of nose
- 14 width of ears
- 15 height of ears

For details look at the literate program of faces

Value

a plot of faces is created on the graphics device, no numerical results

```

PlotFdist

Frequency Distribution Plot

Description

This function is designed to give a univariate graphic representation of a numeric vector's frequency distribution. It combines a histogram, a density curve, a boxplot and a plot of the empirical cumulative distribution function (ecdf) in one single plot, resulting in a dense and informative picture of the facts. Still the function remains flexible as all possible arguments can be passed to the single components (hist, boxplot etc.) by list (see examples).

Usage

```
PlotFdist(x, main = deparse(substitute(x)), xlab = "", xlim = NULL,
  do.hist = !(all(IsWhole(x, na.rm = TRUE)) & length(unique(na.omit(x))) < 13),
  args.hist = NULL, args.rug = NA, args.dens = NULL, args.curve = NA,
  args.boxplot = NULL, args.ecdf = NULL, heights = NULL,
  pdist = NULL, na.rm = FALSE, cex.axis = NULL, cex.main = NULL)
```

Arguments

<code>x</code>	the numerical variable, whose distribution is to be plotted.
<code>main</code>	main title of the plot.
<code>xlab</code>	label of the x-axis, defaults to <code>""</code> . (The name of the variable is typically placed in the main title and would be redundant.)
<code>xlim</code>	range of the x-axis, defaults to <code>a.pretty.range(x, na.rm = TRUE)</code> .
<code>do.hist</code>	defines, whether a histogram or a plot with <code>type = "h"</code> should be used. Default is <code>TRUE</code> (meaning a histogram will be plotted), unless <code>x</code> is an integer with less than 13 unique values!
<code>args.hist</code>	list of additional arguments to be passed to the histogram <code>hist()</code> , ignored if <code>do.hist = FALSE</code> . The defaults chosen when setting <code>args.hist = NULL</code> are more or less the same as in hist .
<code>args.rug</code>	list of additional arguments to be passed to the function <code>rug()</code> . Use <code>args.rug = NA</code> if no rug should be added. This is the default. Use <code>args.rug = NULL</code> to add rug with reasonable default values.
<code>args.dens</code>	list of additional arguments to be passed to density. Use <code>args.dens = NA</code> if no density curve should be drawn. The defaults are taken from density .
<code>args.curve</code>	list of additional arguments to be passed to curve . This argument allows to add a fitted distribution curve to the histogram. By default no curve will be added (<code>args.curve = NA</code>). If the argument is set to <code>NULL</code> , a normal curve with <code>mean(x)</code> and <code>sd(x)</code> will be drawn. See examples for more details.
<code>args.boxplot</code>	list of additional arguments to be passed to the boxplot <code>boxplot()</code> . The defaults are pretty much the same as in boxplot .
<code>args.ecdf</code>	list of additional arguments to be passed to <code>ecdf()</code> . Use <code>args.ecdf = NA</code> if no empirical cumulation function should be included in the plot. The defaults are taken from plot.ecdf .
<code>heights</code>	heights of the plotparts, defaults to <code>c(2, 0.5, 1.4)</code> for the histogram, the boxplot and the empirical cumulative distribution function, resp. to <code>c(2, 1.5)</code> for a histogram and a boxplot only.
<code>pdist</code>	distances of the plotparts, defaults to <code>c(0, 0)</code> , say there will be no distance between the histogram, the boxplot and the ecdf-plot. This can be changed for instance in case that the xaxis is to be added to the histogram.
<code>na.rm</code>	logical, should NAs be omitted? Histogram and boxplot could do without this option, but the density-function refuses to plot with missings. Defaults to <code>FALSE</code> .
<code>cex.axis</code>	character extension factor for the axes.
<code>cex.main</code>	character extension factor for the main title. Must be set in dependence of the plot parts in order to get a harmonic view.

  args.boxplot=NA, args.ecdf=NA)
legend(x="topright", legend=c("kernel density", "t-distribution (df=2)"),
  fill=c(hred, "darkgreen"))
```

PlotFun

Plot a Function

Description

Plots mathematical expressions in one variable using the formula syntax.

Usage

```
PlotFun(FUN, args = NULL, from = NULL, to = NULL, by = NULL,
  xlim = NULL, ylim = NULL, polar = FALSE, type = "l",
  col = par("col"), lwd = par("lwd"), lty = par("lty"),
  pch = NA, add = FALSE, ...)
```

Arguments

<code>FUN</code>	a mathematical expression defined using the formula syntax: $f(x) \sim x$.
<code>args</code>	a list of additional parameters defined in the expression besides the independent variable.
<code>from</code> , <code>to</code>	the range over which the function will be plotted.

by	number: increment of the sequence.
xlim, ylim	NULL or a numeric vector of length 2; if non-NULL it provides the defaults for <code>c(from, to)</code> and, unless <code>add = TRUE</code> , selects the x-limits of the plot - see plot.window .
polar	logical. Should polar coordinates be used? Defaults to FALSE.
type	plot type: see plot.default
col	colors of the lines.
lwd	line widths for the lines.
lty	line type of the lines.
pch	plotting 'character', i.e., symbol to use.
add	logical; if TRUE add to an already existing plot; if NA start a new plot taking the defaults for the limits and log-scaling of the x-axis from the previous plot. Taken as FALSE (with a warning if a different value is supplied) if no graphics device is open.
...	the dots are passed to the plot, resp. lines function.

Details

A function can be plotted with [curve](#). This function here adds some more features, one enabling to use a formula for defining the function to plot. This enables as well a parametric equation to be entered straight forward. Parameters of a function can be set separately. The aspect ratio y/x will be set to 1 by default. (See [plot.window](#) for details.)

If axes are not set to FALSE centered axis at a horizontal and vertical position of 0 will be drawn, containing major and minor ticks.

```

PlotHorizBar

Plot Horizontal Bars

Description

A more flexible implementation of plotting horizontal bars with definable start and end points.

Usage

```

PlotHorizBar(from, to, grp = 1, col = "lightgrey", border = "black",
height = 0.6, add = FALSE, ...)

```

Arguments

from	a numeric vector specifying the start of the bars.
to	a numeric vector specifying the end of the bars.
grp	a grouping factor, determining on which line the bar will be printed. The groups start with y=1 and grow.
col	a vector with the colors of the bars. Default is "lightgrey". This will be recycled if necessary.

border	the border color of the bars. Default ist "black". Set this to NA if no border is to be printed.
height	the height of the bars. Defaults to 0.6.
add	logical, if TRUE (default) add bars to current plot.
...	the dots are passed to plot.new.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[barplot](#)

Examples

```
PlotHorizBar( 1:5, 3:8)
```

PlotLinesA

Plot Lines

Description

Plot the columns of one matrix against the columns of another. Adds a legend on the right at the endpoints of lines.

Usage

```
PlotLinesA(x, y, col = 1:5, lty = 1, lwd = 1, lend = par("lend"),
           xlab = NULL, ylab = NULL, xlim = NULL, ylim = NULL,
           cex = 1, cex.legend = 1, main = NULL, grid = TRUE, mar = NULL)
```

Arguments

x, y	vectors or matrices of data for plotting. The number of rows should match. If one of them are missing, the other is taken as y and an x vector of 1:n is used. Missing values (NAs) are allowed.
col	vector of colors. Colors are used cyclically.
lty, lwd, lend	vector of line types, widths, and end styles. The first element is for the first column, the second element for the second column, etc., even if lines are not plotted for all columns. Line types will be used cyclically until all plots are drawn.
xlab, ylab	titles for x and y axes, as in plot .
xlim, ylim	ranges of x and y axes, as in plot .
cex, cex.legend	character expansion factor relative to current par("cex"). Can be set for mat-plot and for the legend text independently.
main	an overall title for the plot.
grid	logical adds an nx by ny rectangular grid to an existing plot.
mar	the margins of the plot.

Details

This function is rather a template, than a function. It wraps `matplot` to generate a lines plot and adds a rather sophisticated legend on the right side, while calculating appropriate margins. A grid option is included (as `panel.first` does not work in `matplot`).

As in `matplot`, the first column of `x` is plotted against the first column of `y`, the second column of `x` against the second column of `y`, etc. If one matrix has fewer columns, plotting will cycle back through the columns again. (In particular, either `x` or `y` may be a vector, against which all columns of the other argument will be plotted.)

Author(s)

Andri Signorell <andri@signorell.net>

`matplot`, `par`

Examples

```
m <- matrix(c(3,4,5,1,5,4,2,6,2), nrow = 3,
            dimnames = list(dose = c("A","B","C"),
                           age  = c("2010","2011","2012")))

PlotLinesA(m, col=c(PalHelsana()), main="Dose ~ age_grp", lwd=3, ylim=c(1, 10))
```

PlotMarDens

Scatterplot with Marginal Densities

Description

Draw a scatter plot with marginal densities on the `x`- and `y`-axis. Groups can be defined by `grp`.

Usage

```
PlotMarDens(x, y, grp = 1, xlim = NULL, ylim = NULL,
            col = rainbow(nlevels(factor(grp))),
            mardens = c("all","x","y"), pch = 1, pch.cex = 1,
            main = "", na.rm = FALSE, args.legend = NULL,
            args.dens = NULL, ...)
```

Arguments

<code>x</code>	numeric vector of <code>x</code> values.
<code>y</code>	numeric vector of <code>y</code> values (of same length as <code>x</code>).
<code>grp</code>	grouping variable(s), typically factor(s), all of the same length as <code>x</code> .
<code>xlim</code>	the <code>x</code> limits of the plot.
<code>ylim</code>	the <code>y</code> limits of the plot.
<code>col</code>	the colors for lines and points. Uses <code>rainbow()</code> colors by default.
<code>mardens</code>	which marginal densities to plot. Can be set to either just <code>x</code> or <code>y</code> , or both (<code>"all"</code> , latter being the default).

<code>pch</code>	a vector of plotting characters or symbols.
<code>pch.cex</code>	magnification to be used for plotting characters relative to the current setting of <code>cex</code> .
<code>main</code>	a main title for the plot, see also title .
<code>na.rm</code>	logical, should NAs be omitted? Defaults to FALSE.
<code>args.legend</code>	list of additional arguments for the legend. <code>args.legend</code> set to NA prevents a legend from being drawn.
<code>args.dens</code>	list of additional arguments to be passed to <code>density</code> . Use <code>args.dens = NA</code> if no density curve should be drawn. The defaults are taken from density .
<code>...</code>	further arguments are passed to the function <code>plot()</code> .

             )
```

PlotMatrix

Scatterplot Matrix

Description

Plots a scatterplot matrix, for which the variables shown horizontally do not necessarily coincide with those shown vertically. If desired, the matrix is divided into several blocks such that it fills more than 1 plot page.

Usage

```
PlotMatrix(x, y = NULL, data = NULL, panel = 1.panel,
  nrows = 0, ncols = nrows, save = TRUE,
  robrange. = FALSE, range. = NULL, pch = NULL, col = 1,
  reference = 0, ltyref = 3, log = "", xaxs = "r", yaxs = "r",
  xaxmar = NULL, yaxmar = NULL, vnames = NULL,
  main = "", cex.points = NA, cex.lab = 0.7, cex.text = 1.3, cex.title = 1,
  bty = "o", oma = NULL, ...)
```

Arguments

<code>x</code>	data for columns (x axis), or formula defining column variables. If it is a formula containing a left hand side, the left side variables will be used last.
<code>y</code>	data or formula for rows (y axis). Defaults to <code>x</code>
<code>data</code>	data.frame containing the variables in case <code>x</code> or <code>y</code> is a formula
<code>panel</code>	a function that generates the marks of the individual panels, see Details. Defaults essentially to <code>points</code> or <code>text</code> depending on the argument <code>pch</code>
<code>nrows</code>	number of rows of panels on a page
<code>ncols</code>	number of columns of panels on a page
<code>save</code>	if <code>y</code> is not provided and <code>save==TRUE</code> , the first row and the last column are suppressed.
<code>robrange.</code>	if <code>TRUE</code> , robust plot ranges will be used
<code>range.</code>	plot ranges, given as a matrix with 2 rows (min, max) and colnames identifying the variables.
<code>pch</code>	plotting character. A vector of integers, characters or strings can also be given for the default panel function
<code>col</code>	color(s) to be used for plotting the observations
<code>reference</code>	coordinates for reference lines to be shown in the panels. A named vector can be used to define a value for each or any variable.
<code>ltyref</code>	line type for reference lines
<code>log</code>	specifies logarithmic scale of axes. "x" asks for log scale on horizontal axis, "y", on vertical axis, "xy", on both axes.
<code>xaxs, yaxs</code>	styles for x and y axis, see par
<code>xaxmar, yaxmar</code>	in which margin should the x- [y-] axis be labelled?
<code>vnames</code>	labels for the variables
<code>main</code>	main title for the plot (to be repeated on each plot page)
<code>cex.points</code>	character expansion for showing the observations
<code>cex.lab, cex.text</code>	character expansion for variable labels in the margin and in the "diagonal", respectively, relative to <code>cex</code>
<code>cex.title</code>	character expansion for the main title
<code>bty</code>	box type for each panel, see par
<code>oma</code>	width of outer margins, ee par
<code>...</code>	further arguments passed to the <code>panel</code> function

Details

If `x` or `y` is a `data.frame`, it is converted to a numerical matrix.

The `panel` function can be user written. It needs ≥ 6 arguments, which are given:

- the values of the horizontal variable,
- the values of the vertical variable,
- the index of the variable shown horizontally, among the `y` variables,
- the index of the variable shown vertically, among the `x` variables,
- argument `pch`, and
- argument `col`

Since large scatterplot matrices lead to tiny panels, `PlotMatrix` splits the matrix into blocks of at most `nrows` rows and `ncols` columns. If these numbers are missing, they default to `nrows=5` and `ncols=6` for landscape pages, and to `nrows=8` and `ncols=5` for portrait pages.

Value

none

PlotMonth

Plot Monthly or Seasonal Effects Of a Univariate Time Series

Description

Plot monthly or seasonal effects of a univariate time series

Usage

```
PlotMonth(x, type = "l", labels, xlab = "", ylab = deparse(substitute(x)), ...)
```

Arguments

<code>x</code>	univariate time series
<code>type</code>	todo
<code>labels</code>	todo
<code>xlab</code>	a title for the x axis: see title .
<code>ylab</code>	a title for the y axis: see title .
<code>...</code>	the dots are passed to the plot command.

PlotMultiDens

Plot Multiple Density Curves

Description

Multiple density curves are plotted on the same plot. The function plots the density curves in the defined colors and linetypes, after having calculated the globally appropriate xlim- and ylim-values. A legend can directly be included.

Usage

```
PlotMultiDens(x, ...)

## Default S3 method:
PlotMultiDens(x, xlim = NULL, ylim = NULL,
              col = rainbow(length(x)),
              lty = "solid", lwd = 1, xlab = "x", ylab = "density",
              args.dens = NULL, args.legend = NULL,
              na.rm = FALSE, flipxy=FALSE, ...)

## S3 method for class 'formula'
PlotMultiDens(formula, data, subset, ...)
```

Arguments

x	a list of vectors whose densities are to be plotted. Uses split to separate a vector by groups. (See examples)
xlim, ylim	xlim, ylim of the plot.
col	colors of the lines, defaults to <code>rainbow(1:length(x))</code> .
lty	line type of the lines.
lwd	line widths for the lines.
xlab, ylab	a title for the x, resp. y axis. Defaults to "x" and "density".

<code>args.dens</code>	list of additional arguments to be passed to the <code>density</code> function. If set to <code>NULL</code> the defaults will be used. Those are <code>n = 4096</code> (2^{12}) and <code>kernel = "epanechnikov"</code> .
<code>args.legend</code>	list of additional arguments to be passed to the <code>legend</code> function. Use <code>args.legend = NA</code> if no legend should be added.
<code>na.rm</code>	should NAs be omitted? Defaults to <code>FALSE</code> .
<code>flipxy</code>	logical, should x- and y-axis be flipped? Defaults to <code>FALSE</code> .
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>...</code>	the dots are passed to <code>plot(...)</code> .

Details

All style arguments, density arguments and data list elements will be recycled if necessary.
The `flipxy` parameter flips x and y-values, so as to plot density curves on the x-axis.

Value

data.frame with 3 columns, containing the `bw`, `n` and `kernel` parameters used for the list elements.
The number of rows correspond to the length of the list `x`.

Note

Consider using:

```
library(lattice)
densityplot( ~ delivery_min | driver, data=d.pizza)
```

as alternative when not all curves should be plotted in the same plot.

# the input of the following function MUST be a numeric list
PlotMultiDens(list(x=x,y=y,z=z))
```

```

PlotMultiDens( x=split(d.pizza$delivery_min, d.pizza$driver), na.rm=TRUE
, main="delivery time ~ driver", xlab="delivery time [min]", ylab="density"
, lwd=1:7, lty=1:7
, panel.first=grid())
# this example demonstrates the definition of different line types and -colors
# an is NOT thought as recommendation for good plotting practice... :-)

# the formula interface
PlotMultiDens(delivery_min ~ driver, data=d.pizza)

# recycling of the density parameters
res <- PlotMultiDens(x=split(d.pizza$temperature, d.pizza$driver),
args.dens = list(bw=c(5,2), kernel=c("rect","epanechnikov")), na.rm=TRUE)
res

# compare bandwidths
PlotMultiDens(x=split(d.pizza$temperature, d.pizza$driver)[1],
args.dens = list(bw=c(1:5)), na.rm=TRUE,
args.legend=NA, main="Compare bw")
legend(x="topright", legend=gettextf("bw = %s", 1:5), fill=rainbow(5))

```

PlotPolar

Plot Values on a Circular Grid

Description

PlotPolar creates a polar coordinate plot of the radius r in function of the angle θ . 0 degrees is drawn at the 3 o'clock position and angular values increase in a counterclockwise direction.

Usage

```

PlotPolar(r, theta = NULL, type = "p", rlim = NULL, main = "", lwd = par("lwd"),
lty = par("lty"), col = par("col"), pch = par("pch"), fill = NA,
cex = par("cex"), mar = c(2, 2, 5, 2), add = FALSE, ...)

```

Arguments

<code>r</code>	a vector of radial data.
<code>theta</code>	a vector of angular data specified in radians.
<code>type</code>	one out of <code>c("p", "l", "h")</code> , the plot type, defined following the definition in plot type. "p" means points, "l" will connect the points with lines and "h" is used to plot radial lines from the center to the points. Default is "p".
<code>rlim</code>	the r limits (r_1 , r_2) of the plot
<code>main</code>	a main title for the plot, see also title .
<code>lwd</code>	a vector of line widths, see par .
<code>lty</code>	a vector of line types, see par .

<code>col</code>	The colors for lines and points. Multiple colors can be specified so that each point can be given its own color. If there are fewer colors than points they are recycled in the standard fashion. Lines will all be plotted in the first colour specified.
<code>pch</code>	a vector of plotting characters or symbols: see points .
<code>fill</code>	fill color, defaults to NA (none).
<code>cex</code>	a numerical vector giving the amount by which plotting characters and symbols should be scaled relative to the default. This works as a multiple of <code>par("cex")</code> . NULL and NA are equivalent to 1.0.
<code>mar</code>	A numerical vector of the form <code>c(bottom, left, top, right)</code> which gives the number of lines of margin to be specified on the four sides of the plot.
<code>add</code>	defines whether points should be added to an existing plot.
<code>...</code>	further arguments are passed to the plot command.

Details

The function is rather flexible and can produce quite a lot of different plots. So is it also possible to create spider webs or radar plots.

```

PlotPyramid

Draw a Back To Back Pyramid Plot

Description

Pyramid plots are a common way to display the distribution of age groups.

Usage

```

PlotPyramid(lx, rx = NA, ylab = "", ylab.x = 0,
            col = c("red", "blue"), border = par("fg"),

```

```

main = "", lxlable = "", rxlab = "",
xlim = NULL, gapwidth = NULL,
xaxt = TRUE, args.grid = NULL, cex.axis = par("cex.axis"),
cex.lab = par("cex.axis"), cex.names = par("cex.axis"), adj = 0.5, ...)

```

Arguments

lx	either a vector or matrix of values describing the bars which make up the plot. If lx is a vector, it will be used to construct the left barplot. If lx is a matrix the first column will be plotted to the left side and the second to the right side. Other columns are ignored.
rx	a vector with the values used to build the right barplot. lx and rx should be of equal length.
ylab	a vector of names to be plotted either in the middle or at the left side of the plot. If this argument is omitted, then the names are taken from the names attribute of lx if this is a vector.
ylab.x	the x-position of the y-labels.
col	the color(s) of the bars. If there are more than one the colors will be recycled.
border	the border color of the bars. Set this to NA if no border is to be plotted.
main	overall title for the plot.
lxlable	a label for the left x axis.
rxlab	a label for the right x axis.
xlim	limits for the x axis. The first value will determine the limit on the left, the second the one on the right.
gapwidth	the width of a gap in the middle of the plot. If set to 0, no gap will be plotted. Default is NULL which will make the gap as wide, as it is necessary to plot the longest ylab.
xaxt	a character which specifies the x axis type. Specifying "n" suppresses plotting of the axis.
args.grid	list of additional arguments for the grid. Set this argument to NA if no grid should be drawn.
cex.axis	expansion factor for numeric axis labels.
cex.lab	expansion factor for numeric variable labels.
cex.names	expansion factor for y labels (names).
adj	one or two values in [0, 1] which specify the x (and optionally y) adjustment of the labels.
...	the dots are passed to the barplot function.

Details

Pyramid plots are a common way to display the distribution of age groups in a human population. The percentages of people within a given age category are arranged in a barplot, typically back to back. Such displays can be used to distinguish males vs. females, differences between two different countries or the distribution of age at different timepoints. The plot type can also be used to display other types of opposed bar charts with suitable modification of the arguments.

```
ylab = LETTERS[1:5], space = 0.3, col = rep(rainbow(5), each=2),
xlim=c(-10,10), args.grid=NA, cex.names=1.5, adj=1,
lxlabs="Group A", rxlabs="Group B", gapwidth=0, ylab.x=-8, xaxt="n")
```

PlotQQ

*QQ-Plot for Any Distribution***Description**

Create a QQ-plot for a variable of any distribution. The assumed underlying distribution can be defined as a function including all required parameters.

Usage

```
PlotQQ(x, qdist, main = NULL, xlab = NULL, ylab = NULL,
       args.qqline = NULL, ...)
```

Arguments

<code>x</code>	the data sample
<code>qdist</code>	the quantile function of the assumed distribution. Can either be given as simple function name or defined as own function using the required arguments. See examples.
<code>main</code>	the main title for the plot. This will be "Q-Q-Plot" by default
<code>xlab</code>	the xlab for the plot
<code>ylab</code>	the ylab for the plot
<code>args.qqline</code>	arguments for the qqline. This will be estimated as a line through the 25% and 75% quantiles, which is the same procedure as qqline does for normal distribution (instead of set it to <code>abline(a = 0, b = 1)</code>). The line defaults are set to <code>col = par("fg")</code> , <code>lwd = par("lwd")</code> and <code>lty = par("lty")</code> . No line will be plotted if <code>args.qqline</code> is set to NA.
<code>...</code>	the dots are passed to the plot function.

Details

The function generates a sequence of points between 0 and 1 and transforms those into quantiles by means of the defined assumed distribution.

Note

The code is inspired by the tip 10.22 "Creating other Quantile-Quantile plots" from R Cookbook and based on R-Core code from the function `qqline`.

PlotRCol

Information plots

Description

The function `PlotPar()` plots the typically used parameters and their values.
`PlotRCol()` plots the R-colors in a dense manner.

Usage

```
PlotRCol(ord = c("hsv", "default"), label = c("text", "hex", "dec"))
PlotPar()
PlotMar()
```

Arguments

<code>ord</code>	the order of the colors, can be either defined by hsv-value or by the R internal color-number
<code>label</code>	label for the colors, can be the colorname (text), the hex-code (#rrggbb) or the decimal RGB-number

Details

`PlotMar()` should plot the margins, but waits for its implementation...

PlotTernary

*Ternary or Triangular Plots.***Description**

PlotTernary plots in a triangle the values of three variables. Useful for mixtures (chemistry etc.).

Usage

```
PlotTernary(x, y = NULL, z = NULL, args.grid = NULL, lbl = NULL, main = "",...)
```

Arguments

x	vector of first variable. Will be placed on top of the triangle.
y	vector of second variable (the right corner).
z	vector of third variable (on the left corner).
args.grid	list of additional arguments for the grid. Set this argument to NA if no grid should be drawn. The usual color and linetype will be used.
main	overall title for the plot.
lbl	the labels for the corner points. Default to the names of x, y, z.
...	the dots are sent to points

PlotTreemap

Create a Treemap

Description

Creates a treemap where rectangular regions of different size, color, and groupings visualize the elements.

Usage

```
PlotTreemap(x, grp = NULL, labels = NULL, cex = 1, text.col = "black",
            col = rainbow(length(x)), labels.grp = NULL, cex.grp = 3,
            text.col.grp = "black", border.grp = "grey50",
            lwd.grp = 5, main = "")
```

Arguments

<code>x</code>	a vector storing the values to be used to calculate the areas of rectangles.
<code>grp</code>	a vector specifying the group (i.e. country, sector, etc.) to which each element belongs.
<code>labels</code>	a vector specifying the labels.
<code>cex</code>	the character extension for the area labels. Default is 1.
<code>text.col</code>	the text color of the area labels. Default is "black".
<code>col</code>	a vector storing the values to be used to calculate the color of rectangles.
<code>labels.grp</code>	a character vector specifying the labels for the groups.
<code>cex.grp</code>	the character extension for the group labels. Default is 3.
<code>text.col.grp</code>	the text color of the group labels. Default is "black".
<code>border.grp</code>	the border color for the group rectangles. Default is "grey50". Set this to NA if no special border is desired.
<code>lwd.grp</code>	the linewidth of the group borders. Default is 5.
<code>main</code>	a title for the plot.

Details

A treemap is a two-dimensional visualization for quickly analyzing large, hierarchical data sets. Treemaps are unique among visualizations because they provide users with the ability to see both a high level overview of data as well as fine-grained details. Users can find outliers, notice trends, and perform comparisons using treemaps. Each data element contained in a treemap is represented with a rectangle, or a cell. Treemap cell arrangement, size, and color are each mapped to an attribute of that element. Treemap cells can be grouped by common attributes. Within a group, larger cells are placed towards the bottom left, and smaller cells are placed at the top right.

Value

returns a list with groupwise organized midpoints in x and y for the rectangles within a group and for the groups themselves.

Author(s)

Andri Signorell <andri@signorell.net>, strongly based on code from Jeff Enos <jeff@kanecap.com>

  col=SetAlpha("white",0.7) )
```

PlotVenn

*Plot a Venn Diagram***Description**

This function produces Venn diagrams for up to 5 datasets.

Usage

```
PlotVenn(x, col = "transparent", plotit = TRUE, labels = NULL)
```

Arguments

x	the list with the sets to be analysed. Those can be factors or something coercable to a factor.
col	the colors for the sets on the plot.
plotit	logical. Should a plot be produced or just the results be calculated.
labels	special labels for the plot. By default the names of the list x will be used. If those are missing, the LETTERS A..E will be chosen. Set this argument to NA, if no labels at all should be plotted.

Details

The function calculates the necessary frequencies and plots the venn diagram.

Value

a list with 2 elements, the first contains a table with the observed frequencies in the given sets. The second returns a data.frame with the xy coordinates for the labels in the venn diagram, the specific combination of factors and the frequency in that intersection area. The latter can be 0 as well.

r.venn

```

PlotViolin

Plot Violins Instead of Boxplots

Description

This function serves the same utility as side-by-side boxplots, only it provides more detail about the different distribution. It plots violins instead of boxplots. That is, instead of a box, it uses the density function to plot the density. For skewed distributions, the results look like "violins". Hence the name.

Usage

```

PlotViolin(x, ...)

## Default S3 method:
PlotViolin(x, ..., horizontal = FALSE, bw = "SJ", na.rm = FALSE,
           names = NULL, args.boxplot = NULL)

## S3 method for class 'formula'
PlotViolin(formula, data = NULL, ..., subset)

```

Arguments

x	Either a sequence of variable names, or a data frame, or a model formula
horizontal	logical indicating if the densityplots should be horizontal; default FALSE means vertical arrangement.
bw	the smoothing bandwidth (method) being used by density . bw can also be a character string giving a rule to choose the bandwidth. See bw.nrd . The default, has been switched from "nrd0" to "SJ", following the general recommendation in Venables & Ripley (2002). In case of a method, the average computed bandwidth is used.
na.rm	logical, should NAs be omitted? The density-function can't do with missings. Defaults to FALSE.
names	a vector of names for the groups.
formula	a formula, such as $y \sim \text{grp}$, where y is a numeric vector of data values to be split into groups according to the grouping variable grp (usually a factor).

<code>data</code>	a <code>data.frame</code> (or list) from which the variables in formula should be taken.
<code>subset</code>	an optional vector specifying a subset of observations to be used for plotting.
<code>...</code>	The dots are passed to polygon . Notably, you can set the color to red with <code>col="red"</code> , and a border color with <code>border="blue"</code>
<code>args.boxplot</code>	list of arguments for a boxplot to be superposed to the densityplot. By default (NULL) a black boxplot will be drawn. Set this to NA to suppress the boxplot.

Value

If a boxplot was drawn then the function returns a list with the following components:

<code>stats</code>	a matrix, each column contains the extreme of the lower whisker, the lower hinge, the median, the upper hinge and the extreme of the upper whisker for one group/plot. If all the inputs have the same class attribute, so will this component.
<code>n</code>	a vector with the number of observations in each group.
<code>conf</code>	a matrix where each column contains the lower and upper extremes of the notch.
<code>out</code>	the values of any data points which lie beyond the extremes of the whiskers.
<code>group</code>	a vector of the same length as <code>out</code> whose elements indicate to which group the outlier belongs.
<code>names</code>	a vector of names for the groups.

Note

This function is based on [violinplot](#) (package **UsingR**). Some adaptations were made in the interface, such as to accept the same arguments as [boxplot](#) does. Moreover the function was extended by the option to have a boxplot superposed.

Author(s)

John Verzani, Andri Signorell <andri@signorell.net>

References

The code is based on the `boxplot` function from R/base.

Examples

```
# make a "violin"
x <- c(rnorm(100), rnorm(50,5))

PlotViolin(x, col = "brown")

par(mfrow=c(1,2))
f <- factor(rep(1:5, 30))
# make a quintet. Note also choice of bandwidth
PlotViolin(x ~ f, col = SetAlpha("steelblue",0.3), bw = "SJ", main="Vertical")

# and the same, but in horizontal arrangement
PlotViolin(x ~ f, col = SetAlpha("steelblue",0.3), bw = "SJ", horizontal = TRUE,
```

```

las=1, main="Horizontal")

# example taken from boxplot
boxplot(count ~ spray, data = InsectSprays, col = "lightgray", main="Boxplot")
PlotViolin(count ~ spray, data = InsectSprays, col = "lightgray", main="Violinplot")

# groupwise densityplots defined the same way as in boxplot
boxplot(len ~ supp*dose, data = ToothGrowth,
        main = "Guinea Pigs' Tooth Growth",
        xlab = "Vitamin C dose mg", ylab = "tooth length",
        col=c("yellow", "orange"), lty=c(1,2)
)

b <- PlotViolin(len ~ supp*dose, data = ToothGrowth,
               main = "Guinea Pigs' Tooth Growth",
               xlab = "Vitamin C dose mg", ylab = "tooth length",
               col=c("yellow", "orange"), lty=c(1,2)
)

# use points, if the medians deserve special attention
points(x=1:6, y=b$stats[3,], pch=21, bg="white", col="black", cex=1.2)

```

PlotWeb

Plot a Web of Connected Points

Description

This plot can be used to graphically display a correlation matrix by using the linewidth between the nodes in proportion to the correlation of two variables. It will place the elements homogenously around a circle and draw connecting lines between the points.

Usage

```

PlotWeb(m, col = c("red", "blue"), lty = par("lty"), args.legend=NULL,
       pch = 21, pt.cex = 2, pt.col = "black", pt.bg = "darkgrey", ...)

```

Arguments

<code>m</code>	a matrix with numeric values
<code>col</code>	the color for the connecting lines
<code>lty</code>	the line type for the connecting lines
<code>args.legend</code>	list of additional arguments to be passed to the legend function. Use <code>args.legend = NA</code> if no legend should be added.
<code>pch</code>	the plotting symbols appearing in the plot, as a non-negative numeric vector (see points , but unlike there negative values are omitted) or a vector of 1-character strings, or one multi-character string.
<code>pt.cex</code>	expansion factor(s) for the points.
<code>pt.col</code>	the foreground color for the points, corresponding to its argument <code>col</code> .
<code>pt.bg</code>	the background color for the points, corresponding to its argument <code>bg</code> .
<code>...</code>	dots are passed to plot.

Value

A list of x and y coordinates, giving the coordinates of all the points drawn, useful for adding to the graph.

m <- cor(d.pizza[, which(sapply(d.pizza, IsNumeric, na.rm=TRUE))[-c(1:2)]],
        use="pairwise.complete.obs")
PlotWeb(m=m, col=c("red","blue"), main="Pizza Correlation")

# let's describe only the significant corrs and start with a dataset
d.m <- d.pizza[, which(sapply(d.pizza, IsNumeric, na.rm=TRUE))[-c(1:2)]]

# get the correlation matrix
m <- cor(d.m, use="pairwise.complete.obs")

# let's get rid of all non significant correlations
ctest <- PairApply(d.m, function(x, y) cor.test(x, y)$p.value, symmetric=TRUE)

# ok, got all the p-values, now replace > 0.05 with NAs
m[ctest > 0.05] <- NA
# How does that look like now?
noquote(Format(m, na.form = ". ", leading="drop", digits=3, align = "right"))

PlotWeb(m)
```

PoissonCI

Poisson Confidence Interval

Description

Computes the confidence intervals of a poisson distributed variable's lambda. Several methods are implemented, see details.

Usage

```
PoissonCI(x, n = 1, conf.level = 0.95, method = c("exact", "score", "wald"))
```

Arguments

x	number of events.
n	time base for event count.
conf.level	confidence level, defaults to 0.95.
method	character string specifying which method to use; can be one out of "wald", "score". Method can be abbreviated. See details. Defaults to "score".

Details

The Wald interval uses the asymptotic normality of the test statistic.

Value

A vector with 3 elements for estimate, lower confidence interval and upper for the upper one.

PolarGrid

*Plot a Grid in Polar Coordinates***Description**

PolarGrid adds a polar grid to an existing plot. The number of radial gridlines are set by `ntheta` and the tangential lines by `nr`.

Usage

```
PolarGrid(nr = NULL, ntheta = NULL, col = "lightgray", lty = "dotted", lwd = par("lwd"),
          rlabels = NULL, alabels = NULL, lblradians = FALSE)
```

Arguments

<code>nr</code>	number of circles. When <code>NULL</code> , as per default, the grid aligns with the tick marks on the corresponding default axis (i.e., tickmarks as computed by <code>axTicks</code>). When <code>NA</code> , no circular grid lines are drawn.
<code>ntheta</code>	number of radial grid lines. Defaults to 12 uniformly distributed between 0 and 2π (each $\pi/3$).
<code>col</code>	character or (integer) numeric; color of the grid lines.
<code>lty</code>	character or (integer) numeric; line type of the grid lines.
<code>lwd</code>	non-negative numeric giving line width of the grid lines.
<code>rlabels</code>	the radius labels. Use <code>NA</code> if no labels should be to be added.
<code>alabels</code>	the labels for the angles, they are printed on a circle outside the plot. Use <code>NA</code> for no angle labels.
<code>lblradians</code>	logic, defines if angle labels will be in degrees (default) or in radians.

Details

This can be made better...

```

PostHocTest	<i>Post-Hoc Tests</i>
-------------	-----------------------

Description

A convenience wrapper for computing post-hoc test after having calculated an ANOVA.

Usage

```
PostHocTest(x, ...)

## S3 method for class 'aov'
PostHocTest(x, which = NULL,
            method = c("hsd", "bonferroni", "lsd", "scheffe", "newmankeuls", "duncan"),
            conf.level = 0.95, ordered = FALSE, ...)

## S3 method for class 'table'
PostHocTest(x, method = c("none", "fdr", "BH", "BY", "bonferroni",
                          "holm", "hochberg", "hommel"),
            conf.level = 0.95, ...)

## S3 method for class 'PostHocTest'
print(x, digits = getOption("digits"), ...)
## S3 method for class 'PostHocTest'
plot(x, ...)
```

Arguments

<code>x</code>	an aov object.
<code>method</code>	one of "hsd", "bonf", "lsd", "scheffe", "newmankeuls", defining the method for the pairwise comparisons. For the post hoc test of tables the methods of p.adjust can be supplied. See the detail there.
<code>which</code>	a character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.
<code>conf.level</code>	a numeric value between zero and one giving the family-wise confidence level to use. If this is set to NA, just a matrix with the p-values will be returned.
<code>ordered</code>	a logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If ordered is TRUE then the calculated differences in the means will all be positive. The significant differences will be those for which the lower end point is positive. This argument will be ignored if method is not either hsd or newmankeuls.
<code>digits</code>	controls the number of digits to print.
<code>...</code>	further arguments, not used so far.

Details

The function is designed to consolidate a couple of post-hoc tests with the same interface for input and output.

Choosing Tests

Different Post Hoc tests use different methods to control FW and PE. Some tests are very conservative. Conservative tests go to great lengths to prevent the user from committing a Type I error. They use more stringent criterion for determining significance. Many of these tests become more and more stringent as the number of groups increases (directly limiting the FW and PE error rate). Although these tests buy you protection against Type I error, it comes at a cost. As the tests become more stringent, you lose Power (1-B). More Liberal tests, buy you Power but the cost is an increased chance of Type I error. There is no set rule for determining which test to use, but different researchers have offered some guidelines for choosing. Mostly it is an issue of pragmatics and whether the number of comparisons exceeds $K-1$.

Fisher's LSD

The Fisher LSD (Least Significant Different) sets Alpha Level per comparison. $\alpha = .05$ for every comparison. $df = df_{\text{error}}$ (i.e. df_{within}). This test is the most liberal of all Post Hoc tests. The critical t for significance is unaffected by the number of groups. This test is appropriate when you have 3 means to compare. In general the α is held at .05 because of the criterion that you can't look at LSD's unless the Anova is significant. This test is generally not considered appropriate if you have more than 3 means unless there is reason to believe that there is no more than one true Null Hypothesis hidden in the means.

Dunn's (Bonferroni)

Dunn's t -test is sometimes referred to as the Bonferroni t because it used the Bonferroni PE correction procedure in determining the critical value for significance. In general, this test should be used when the number of comparisons you are making exceeds the number of degrees of freedom you have between groups (e.g. $K-1$). This test sets α per experiment; $\alpha = (.05)/c$ for every comparison. $df = df_{\text{error}}$ ($c = \text{number of comparisons } (K(K-1))/2$) This test is extremely conservative and rapidly reduces power as the number of comparisons being made increase.

Newman-Keuls

Newman-Keuls is a step down procedure that is not as conservative as Dunn's t test. First, the means of the groups are ordered (ascending or descending) and then the largest and smallest means are tested for significant differences. If those means are different, then test smallest with next largest, until you reach a test that is not significant. Once you reach that point then you can only test differences between means that exceed the difference between the means that were found to be non-significant. Newman-Keuls is perhaps one of the most common Post Hoc test, but it is a rather controversial test. The major problem with this test is that when there is more than one true Null Hypothesis in a set of means it will overestimate the FW error rate. In general we would use this when the number of comparisons we are making is larger than $K-1$ and we don't want to be as conservative as the Dunn's test is.

Tukey's HSD

Tukey HSD (Honestly Significant Difference) is essentially like the Newman-Keul, but the tests between each mean are compared to the critical value that is set for the test of the means that are furthest apart (e.g. if there are 5 means we use the critical value determined for the test of X_1 and X_5). This Method corrects for the problem found in the Newman-Keuls where the FW is inflated when there is more than one True Null Hypothesis in a set of means. It buys protection against Type I error, but again at the cost of Power. It tends to be the most common test and preferred test because it is very conservative with respect to Type I error when the Null hypothesis is true. In general, HSD is preferred when you will make all the possible comparisons between a large set of means (Six or more means).

Scheffe

The Scheffe Test is designed to protect against a Type I error when all possible complex and simple comparisons are made. That is we are not just looking the possible combinations of comparisons between pairs of means. We are also looking at the possible combinations of comparisons between groups of means. Thus Scheffe is the most conservative of all tests. Because this test does give us the capacity to look at complex comparisons, it essentially uses the same statistic as the Linear Contrasts tests. However, Scheffe uses a different critical value (or at least it makes an adjustment to the critical value of F). This test has less power than the HSD when you are making Pairwise (simple) comparisons, but it has more power than HSD when you are making Complex comparisons. In general, only use this when you want to make many Post Hoc complex comparisons (e.g. more than K-1).

Tables

For tables pairwise chi-square test can be performed, either without correction or with correction for multiple testing following the logic in [p.adjust](#).

Value

an object of type "PostHocTest", which will either be

A) a list of data.frames containing the mean difference, lower ci, upper ci and the p-value, if a conf.level was defined (something else than NA) or

B) a list of matrices with the p-values, if conf.level has been set to NA.

Author(s)

Andri Signorell <andri@signorell.net>

[TukeyHSD](#), [aov](#), [pairwise.t.test](#), [ScheffeTest](#)

Examples

```
PostHocTest(aov(breaks ~ tension, data = warpbreaks), method = "lsd")
PostHocTest(aov(breaks ~ tension, data = warpbreaks), method = "hsd")
PostHocTest(aov(breaks ~ tension, data = warpbreaks), method = "scheffe")

r.aov <- aov(breaks ~ tension, data = warpbreaks)

# compare p-values:
round(cbind(
  lsd= PostHocTest(r.aov, method="lsd")$tension[, "pval"]
  , bonf=PostHocTest(r.aov, method="bonf")$tension[, "pval"]
), 4)

# only p-values by setting conf.level to NA
PostHocTest(aov(breaks ~ tension, data = warpbreaks), method = "hsd",
  conf.level=NA)
```

Description

Compute power of test or determine parameters to obtain target power (same as power.anova.test).

Usage

```
power.chisq.test(w = NULL, N = NULL, df = NULL, sig.level = 0.05, power = NULL)
```

Arguments

w	Effect size
N	Total number of observations
df	degree of freedom (depends on the chosen test)
sig.level	Significance level (Type I error probability)
power	Power of test (1 minus Type II error probability)

Details

Exactly one of the parameters 'w','N','power' and 'sig.level' must be passed as NULL, and that parameter is determined from the others. Notice that the last one has non-NULL default so NULL must be explicitly passed if you want to compute it.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with 'method' and 'note' elements.

Note

'uniroot' is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

```

Description

A couple of functions to get R-stuff into MS-Powerpoint. PpAddSlide inserts a new slide into the active presentation.

PpPlot inserts the active plot into PowerPoint. The image is transferred by saving the picture to a file in R and inserting the file in PowerPoint. The format of the plot can be selected, as well as crop options and the size factor for inserting.

PpText inserts a new textbox with given text and box properties.

Usage

```
PpAddSlide(pos = NULL, pp = getOption("lastPP"))

PpPlot(type = "png", crop = c(0, 0, 0, 0), picscale = 100, x = 1, y = 1,
        height = NA, width = NA, res=200, dfact=1.6, pp = getOption("lastPP"))

PpText(txt, x = 1, y = 1, height = 50, width = 100, fontname = "Calibri", fontsize = 18,
        bold = FALSE, italic = FALSE, col = "black", bg = "white",
        hasFrame = TRUE, pp = getOption("lastPP"))
```

Arguments

pos	position of the new inserted slide.
type	the format for the picture file, default is "png".
crop	crop options for the picture, defined by a 4-elements-vector. The first element is the bottom side, the second the left and so on.
picscale	scale factor of the picture in percent, default ist 100.
x, y	left/upper xy-coordinate for the plot or for the textbox.
height	height in cm, this overrides the picscale if both are given.
width	width in cm, this overrides the picscale if both are given.
res	resolution for the png file, defaults to 200.
dfact	the size factor for the graphic.
txt	text to be placed in the textbox
fontname	used font for textbox
fontsize	used fontsize for textbox
bold	logic. Text is set bold if this is set to TRUE (default is FALSE).
italic	logic. Text is set italic if this is to TRUE (default is FALSE).
col	font color, defaults to "black".
bg	background color for textboxdefaults to "white".
hasFrame	logical. Defines if a textbox is to be framed. Default is TRUE.
pp	the pointer to a PowerPoint instance, can be a new one, created by GetNewPP() or the last created by getOption("lastPP") (default).

Details

See PowerPoint-objectmodel for further informations.

Value

Returns a pointer to the inserted picture.

Author(s)

Andri Signorell <andri@signorell.net>

## End(Not run)
```

pRevGumbel	<i>"Reverse" Gumbel Distribution Functions</i>
------------	--

Description

Density, distribution function, quantile function and random generation for the “Reverse” Gumbel distribution with parameters location and scale.

Usage

```
dRevGumbel (x, location = 0, scale = 1)
pRevGumbel (q, location = 0, scale = 1)
qRevGumbel (p, location = 0, scale = 1)
rRevGumbel (n, location = 0, scale = 1)

qRevGumbelExp(p)
```

Arguments

x, q	numeric vector of abscissa (or quantile) values at which to evaluate the density or distribution function.
p	numeric vector of probabilities at which to evaluate the quantile function.
location	location of the distribution
scale	scale (> 0) of the distribution.
n	number of random variates, i.e., length of resulting vector of <code>rRevGumbel(...)</code> .

Value

a numeric vector, of the same length as x, q, or p for the first three functions, and of length n for `rRevGumbel()`.

Author(s)

Werner Stahel; partly inspired by package **VGAM**. Martin Maechler for numeric cosmetic.

See Also

the [Weibull](#) distribution functions in R's **stats** package.

Examples

```

curve(pRevGumbel(x, scale= 1/2), -3,2, n=1001, col=1, lwd=2,
      main = "RevGumbel(x, scale = 1/2)")
abline(h=0:1, v = 0, lty=3, col = "gray30")
curve(dRevGumbel(x, scale= 1/2),      n=1001, add=TRUE,
      col = (col.d <- adjustcolor(2, 0.5)), lwd=3)
legend("left", c("cdf","pdf"), col=c("black", col.d), lwd=2:3, bty="n")

med <- qRevGumbel(0.5, scale=1/2)
cat("The median is:", format(med),"\n")

```

Primes

Find all Primes Less Than n

Description

Find all prime numbers aka ‘primes’ less than n .

Uses an obvious sieve method and some care, working with logicals and integers to be quite fast.

Usage

```
Primes(n)
```

Arguments

n a (typically positive integer) number.

Details

As the function only uses `max(n)`, n can also be a *vector* of numbers.

Value

numeric vector of all prime numbers $\leq n$.

Note

This function was previously published in the package `sfsmisc` as `primes` and has been integrated here without logical changes.

Author(s)

Bill Venables ($\leq n$); Martin Maechler gained another 40% speed, working with logicals and integers.

See Also

[Factorize](#)

Examples

```
(p1 <- Primes(100))
system.time(p1k <- Primes(1000)) # still lightning ..

stopifnot(length(p1k) == 168)
```

PtInPoly

*Point in Polygon***Description**

PtInPoly works out if 2D points lie within the boundaries of a defined polygon.

Note: Points that lie on the boundaries of the polygon or vertices are assumed to be within the polygon.

Usage

```
PtInPoly(pnts, poly.pnts)
```

Arguments

pnts	a 2-column matrix or dataframe defining locations of the points of interest
poly.pnts	a 2-column matrix or dataframe defining the locations of vertices of the polygon of interest

Details

The algorithm implements a sum of the angles made between the test point and each pair of points making up the polygon. The point is interior if the sum is 2π , otherwise, the point is exterior if the sum is 0. This works for simple and complex polygons (with holes) given that the hole is defined with a path made up of edges into and out of the hole.

This sum of angles is not able to consistently assign points that fall on vertices or on the boundary of the polygon. The algorithm defined here assumes that points falling on a boundary or polygon vertex are part of the polygon.

Value

A 3-column dataframe where the first 2 columns are the original locations of the points. The third column (names pip) is a vector of binary values where 0 represents points not with the polygon and 1 within the polygon.

Author(s)

Jeremy VanDerWal <jjvanderwal@gmail.com>

Examples

```
#define the points and polygon
pnts <- expand.grid(x=seq(1,6,0.1), y=seq(1,6,0.1))
polypnts <- cbind(x=c(2,3,3.5,3.5,3,4,5,4,5,5,4,3,3,3,2,2,1,1,1,1,2),
                 y=c(1,2,2.5,2,2,1,2,3,4,5,4,5,4,3,3,4,5,4,3,2,2) )

#plot the polygon and all points to be checked
plot(rbind(polypnts, pnts))
polygon(polypnts, col='#99999990')

#create check which points fall within the polygon
out <- PtInPoly(pnts, polypnts)
head(out)

#identify points not in the polygon with an X
points(out[which(out$pip==0), 1:2], pch='X')
```

Ray

*Compact Information About the Columns of a Data Frame***Description**

An alternative description of a data.frame.

Usage

```
Ray(x)
```

Arguments

x a data.frame to be described.

Details

I always missed the index of the variables in [str](#)...

Value

a list with the results

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[str](#), [summary](#)

Examples

```
Ray(d.pizza)
```

Recode

*Recode a Factor***Description**

Combining or rearranging a factor can be tedious if it has many levels. Recode supports this step by accepting a direct definition of newlevels by oldlevels as argument and adding an "elselevel" option.

Usage

```
Recode(x, newlevels, elselevel = NA, use.empty = FALSE)
```

Arguments

<code>x</code>	the factor whose levels are to be altered.
<code>newlevels</code>	a list with the oldlevels combined by <code>c()</code> and named with the name of the new level: <code>list(newlevel_a=c("old_a", "old_b"), newlevel_b=c("old_c", "old_d"))</code> . See examples.
<code>elselevel</code>	how should the levels, which are not matched by newlevel's list be named. Set this to <code>NULL</code> , if elselevels should be left unchanged. Defaults to <code>NA</code> .
<code>use.empty</code>	logical. Defines how a new level, which can't be found in <code>x</code> , should be handled. Should it be left in the level's list or be dropped? The default is <code>FALSE</code> , which drops empty levels.

Value

the factor having the new levels applied.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[factor](#), [levels](#)

There's another possible solution in the package `car`.

Examples

```
x <- factor(sample(letters, 20))

y <- Recode( x, newlevels=list(
  "good" = c("a","b","c"),          # the old levels "a","b","c" get the new level "good"
  "bad"  = c("d","e","f"),          # the old levels "d","e","f" get the new level "bad" etc.
  "ugly" = c("g","h","k")), elselevel="other")

data.frame(x, y)

x <- factor(letters[1:6])
```

```

z1 <- Recode(x, newlevels=list("AB"=c("a","b"), "CD"=c("c","d")), elselevel="none of these")
z2 <- Recode(x, newlevels=list("AB"=c("a","b"), "CD"=c("c","d")), elselevel=NA)
z3 <- Recode(x, newlevels=list("AB"=c("a","b"), "CD"=c("c","d")), elselevel=NULL)
z4 <- Recode(x, newlevels=list("AB"=c("a","b"), "GH"=c("g","h")), elselevel=NA, use.empty=TRUE)
z5 <- Recode(x, newlevels=list("AB"=c("a","b"), "GH"=c("g","h")), elselevel=NA, use.empty=FALSE)

data.frame(z1, z2, z3, z4, z5)

# empty level GH in z4...
table(z4, useNA="ifany")
# but not in z5
table(z5, useNA="ifany")

```

Recycle

Recycle a List of Elements

Description

This function recycles all supplied elements to the maximal dimension.

Usage

```
Recycle(...)
```

Arguments

... a number of vectors of elements.

Value

a list of the supplied elements

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[rep](#), [replicate](#)

Examples

```
Recycle(x=1:5, y=1, s=letters[1:2])
```

RelRisk	<i>Relative Risk</i>
---------	----------------------

Description

Computes the relative risk and it's confidence intervals. Confidence intervals are calculated using normal approximation ("wald"), ("score") or by using oddsratio ("use.or")

Usage

```
RelRisk(x, y = NULL, conf.level = NA,
        method = c("score", "wald", "use.or"), delta = 0.5, ...)
```

Arguments

x	a numeric vector or a 2x2 numeric matrix, resp. table.
y	NULL (default) or a vector with compatible dimensions to x. If y is provided, table(x, y, ...) will be calculated.
conf.level	confidence level. Default is NA, meaning no confidence intervals will be reported.
method	method for calculating odds ratio and confidence interval. Can be one out of "score", "wald", "use.or". Default is "score".
delta	small constant to be added to the numerator for calculating the log risk ratio (Wald method). Usual choice is 0.5 although there does not seem to be any theory behind this. (Dewey, M. 2006)
...	further arguments are passed to the function table , allowing i.e. to set useNA.

Details

This function expects the following table structure:

	disease=0	disease=1
exposed=0 (ref)	n00	n01
exposed=1	n10	n11

If the table to be provided is not in the preferred form, use the function [Rev\(\)](#) to "reverse" the table rows, -columns, or both.

Value

If conf.level is not NA then the result will be a vector with 3 elements for estimate, lower confidence intervall and upper for the upper one. Else the relative risk will be reported as a single value.

Author(s)

Andri Signorell <andri@signorell.net>, based on code of Yongyi Min and Michael Dewey

Rename	<i>Change Names of a Named Object</i>
--------	---------------------------------------

Description

Rename changes the names of a named object.

Usage

```
Rename(x, ..., gsub = FALSE, fixed = TRUE, warn = TRUE)
```

Arguments

x	Any named object
...	A sequence of named arguments, all of type character
gsub	a logical value; if TRUE, gsub is used to change the row and column labels of the resulting table. That is, instead of substituting whole names, substrings of the names of the object can be changed.
fixed	a logical value, passed to gsub . If TRUE, substitutions are by fixed strings and not by regular expressions.
warn	a logical value; should a warning be issued if those names to change are not found?

Details

This function changes the names of x according to the remaining arguments. If gsub is FALSE, argument tags are the *old* names, the values are the new names. If gsub is TRUE, arguments are substrings of the names that are substituted by the argument values.

Value

The object `x` with new names defined by the `...` arguments.

Note

This function was previously published in the package **memisc** as [rename](#) and has been integrated here without logical changes.

Author(s)

Martin Elff <melff@essex.ac.uk>

            Sepal.Length="Sepal_Length",
            Sepal.Width ="Sepal_Width",
            Petal.Length="Petal_Length",
            Petal.Width ="Petal_Width"
          ))

str(Rename(iris, .="_", gsub=TRUE))
```

reorder.factor

Reorder the Levels of a Factor

Description

Reorder the levels of a factor

Usage

```
## S3 method for class 'factor'
reorder(x, X, FUN, ...,
        order = is.ordered(x), new.order, sort = SortMixed)
```

Arguments

<code>x</code>	factor
<code>X</code>	auxillary data vector
<code>FUN</code>	function to be applied to subsets of <code>X</code> determined by <code>x</code> , to determine factor order
<code>...</code>	optional parameters to <code>FUN</code>
<code>order</code>	logical value indicating whether the returned object should be an ordered factor

<code>new.order</code>	a vector of indexes or a vector of label names giving the order of the new factor levels
<code>sort</code>	function to use to sort the factor level names, used only when <code>new.order</code> is missing

Details

This function changes the order of the levels of a factor. It can do so via three different mechanisms, depending on whether, *X and FUN*, `new.order` or `sort` are provided.

If *X and Fun* are provided: The data in *X* is grouped by the levels of *x* and *FUN* is applied. The groups are then sorted by this value, and the resulting order is used for the new factor level names.

If `new.order` is provided: For a numeric vector, the new factor level names are constructed by reordering the factor levels according to the numeric values. For vectors, `new.order` gives the list of new factor level names. In either case levels omitted from `new.order` will become missing (NA) values.

If `sort` is provided (as it is by default): The new factor level names are generated by applying the supplied function to the existing factor level names. With `sort=mixedsort` the factor levels are sorted so that combined numeric and character strings are sorted in according to character rules on the character sections (including ignoring case), and the numeric rules for the numeric sections. See [mixedsort](#) for details.

Value

A new factor with reordered levels

# drop out the '300 MG' level
trt6 <- reorder(trt, new.order=c("PLACEBO", "600 MG", "1200 MG"))
summary(trt6)
```

Rev*Reverse Elements of a Vector or the Rows/Columns of Matrices and Tables*

Description

Rev provides a reversed version of its argument. It wraps the base function `rev` and provides an additional method for matrices and higher dimensional tables, such as to reverse the order of rows and columns.

Usage

```
Rev(x, ...)

## S3 method for class 'matrix'
Rev(x, margin, ...)

## S3 method for class 'table'
Rev(x, margin, ...)
```

Arguments

<code>x</code>	a vector, a matrix or a higher dimensional table to be reversed.
<code>margin</code>	vector of dimensions which to be reversed (1 for rows, 2 for columns, etc.).
<code>...</code>	the dots are passed to the matrix, resp. table interface.

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
tab <- matrix( c( 1, 11, 111,
                  2, 22, 222,
                  3, 33, 333), byrow=TRUE, nrow=3)

Rev(tab, margin=1)
Rev(tab, margin=2)

# reverse both dimensions
Rev(tab, margin=c(1,2))
```

RgbToCol*Find the Named R-Color Which Is Nearest to a Given RGB-Color*

Description

Convert a RGB-color to a named R-Color means looking for a color in the R-palette, which is nearest to the given RGB-color. The function uses the minimum of squared distance as proximity measure.

RgbToLong converts an RGB-color to a long integer in numeric format.

Usage

```
RgbToCol(col, method = "rgb", metric = "euclidean")  
RgbToLong(col)
```

Arguments

col	the color in rgb code, say a matrix with the red, green and blue code in the rows.
method	character string specifying the color space to be used. Can be "rgb" (default) or "hsv".
metric	character string specifying the metric to be used for calculating distances between the colors. Available options are "euclidean" (default) and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.

Value

the name of the nearest found R color.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[ColToRgb](#) and the other conversion functions

Examples

```
RgbToCol(matrix(c(162,42,42), nrow=3))  
RgbToLong(matrix(c(162,42,42), nrow=3))
```

RndPairs

Create Pairs of Correlated Random Numbers

Description

Create pairs of correlated random numbers.

Usage

```
RndPairs(n, r, rdist1 = rnorm(n = n, mean = 0, sd = 1),  
         rdist2 = rnorm(n = n, mean = 0, sd = 1))
```

```
SampleWord(size, length, x = LETTERS, replace = TRUE)
```

Arguments

n	number of pairs. If length(n) > 1, the length is taken to be the number required.
r	the correlation between the two sets.
rdist1, rdist2	the distribution of the random vector X1 and X2. Default is standard normal distribution.
size	a non-negative integer giving the number of artificial words to build.
length	a non-negative integer giving the length of the words.
x	elements to choose from.
replace	Should sampling be with replacement?

Value

a data.frame with 2 columns, X1 and X2 containing the random numbers

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[runif](#), [rnorm](#), [Random](#) and friends

Examples

```
# produce 100 pairs of a normal distributed random number with a correlation of 0.7  
d.frm <- RndPairs(n=100, r=0.7)  
  
plot(d.frm)  
lines(lm(X2 ~ X1,d.frm))  
  
# change the distribution  
d.frm <- RndPairs(n=100, r=0.7, rdist2 = rlnorm(n = 100, meanlog = 1, sdlog = .8))  
d.frm <- RndPairs(n=100, r=0.7, rdist2 = runif(n = 100, -1, 4))
```

RobRange*Robust Range*

Description

Determines a robust range of the data on the basis of the trimmed mean and variance.

Usage

```
RobRange(x, trim = 0.2, fac = 3, na.rm = FALSE)
```

Arguments

<code>x</code>	a vector of data.
<code>trim</code>	the fraction (0 to 0.5) of observations to be trimmed from each end of <code>x</code> before the mean is computed. Values of <code>trim</code> outside that range are taken as the nearest endpoint. Default is 0.2.
<code>fac</code>	factor used for expanding the range, see Details. Default is 3.
<code>na.rm</code>	a logical value indicating whether NA values should be stripped before the computation proceeds.

Details

The function determines the trimmed mean `m` and then the "upper trimmed mean" `s` of absolute deviations from `m`, multiplied by `fac`. The robust minimum is then defined as `m-fac*s` or `min(x)`, whichever is larger, and similarly for the maximum.

Value

The robust range.

Author(s)

Werner Stahel, ETH Zurich

Examples

```
x <- c(rnorm(20), rnorm(3, 5, 20))
RobRange(x)

# compared to:
range(x)
```

RobScale*Robust Scaling With Median and Mad*

Description

RobScale is a wrapper function for robust standardization, using `median` and `mad` instead of `mean` and `sd`.

Usage

```
RobScale(x, center = TRUE, scale = TRUE)
```

Arguments

<code>x</code>	a numeric matrix(like object).
<code>center</code>	a logical value defining whether <code>x</code> should be centered by the median. Centering is done by subtracting the column medians (omitting NAs) of <code>x</code> from their corresponding columns. If <code>center</code> is <code>FALSE</code> , no centering is done.
<code>scale</code>	a logical value defining whether <code>x</code> should be scaled by the <code>mad</code> . Scaling is done by dividing the (centered) columns of <code>x</code> by their <code>mad</code> . If <code>scale</code> is <code>FALSE</code> , no scaling is done.

Value

the centered, scaled matrix. The numeric centering and scalings used (if any) are returned as attributes "scaled:center" and "scaled:scale"

Author(s)

Andri Signorell <andri@signorell.net>

See Also

`scale`, `sweep`

Examples

```
x <- d.pizza$temperature
plot(x=seq_along(x), y=RobScale(x), xlim=c(0,100))
points(x=seq_along(x), y=scale(x), col="red" )
```

 Rotate

Rotate a Geometric Structure

Description

Rotate a geometric structure by an angle θ around a centerpoint xy .

Usage

```
Rotate(x, y, mx = 0, my = 0, theta = pi/3)
```

Arguments

x, y	a vector of xy -coordinates of the geometric structure, which has to be rotated
mx, my	xy -coordinates of the center of the rotation.
θ	angle of the rotation

Value

The function invisibly returns a list of the coordinates for the rotated shape(s).

Author(s)

Andri Signorell <andri@signorell.net>

x <- DrawRegPolygon(nv=3)[[1]]

# and rotate
sapply( (0:3) * pi/6, function(theta) {
  xy <- Rotate( x=x$x, y=x$y, theta=theta )
  polygon(xy$x, xy$y, col=SetAlpha("blue", 0.2))
} )

abline(v=0,h=0)
```

RoundM*Round to Multiple*

Description

Returns a number rounded to the desired multiple.

Usage

```
RoundM(x, multiple = 1, FUN = round)
```

Arguments

x	numeric. The value to round.
multiple	numeric. The multiple to which the number is to be rounded. Default is 1.
FUN	the rounding function as character or as expression. Can be one out of ceiling, round or floor. Default is round.

Details

RoundM rounds up, away from zero, if the remainder of dividing number by multiple is greater than or equal to half the value of multiple if FUN is set to round. If FUN is ceiling it will always round up, and if FUN is floor it will always round down.

Value

the rounded value

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[round](#), [ceiling](#), [floor](#)

Examples

```

RoundM(1.3, 0.2)   # Rounds 1.3 to a nearest multiple of 0.2 (1.2)
RoundM(5, -2)      # Returns an error, because -2 and 5 have different signs

RoundM(c(1.92, 45.38, 0.831125), 0.05, ceiling)
RoundM(c(1.92, 45.38, 0.831125), 0.05, round)
RoundM(c(1.92, 45.38, 0.831125), 0.05, floor)
```

RunsTest

*Runs Test for Randomness***Description**

Performs a one sample runs test or a two sample Wald-Wolfowitz-Test on vectors of data.

Usage

```
RunsTest(x, ...)

## Default S3 method:
RunsTest(x, y = NULL, alternative = c("two.sided", "less", "greater"),
        exact = NULL, na.rm = FALSE, ...)

## S3 method for class 'formula'
RunsTest(formula, data, subset, na.action, ...)
```

Arguments

x	a dichotomous vector of data values or a (non-empty) numeric vector of data values.
y	an optional (non-empty) numeric vector of data values.
formula	a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
data	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from <code>environment(formula)</code> .
subset	an optional vector specifying a subset of observations to be used.
na.action	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
alternative	a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "less" or "greater".
exact	a logical indicating whether an exact p-value should be computed. By default exact values will be calculated for small vectors with a total length ≤ 30 .
na.rm	defines if NAs should be omitted. Default is FALSE.
...	further arguments to be passed to or from methods.

Details

The runs test for randomness is used to test the hypothesis that a series of numbers is random. The 2-sample test is known as the Wald-Wolfowitz test.

For a categorical variable, the number of runs correspond to the number of times the category changes, that is, where x_i belongs to one category and x_{i+1} belongs to the other. The number of runs, is the number of sign changes plus one.

For a numeric variable x containing more than two values, a run is a set of sequential values that are either all above or below a specified cutpoint, typically the median.

Value

A list with the following components.

statistic	z, the value of the standardized runs statistic, if not exact p-values are computed.
parameter	the number of runs, the total number of zeros (m) and ones (n)
p.value	the p-value for the test.
data.name	a character string giving the names of the data.
alternative	a character string describing the alternative hypothesis.

RunsTest(A, B, exact=TRUE)
RunsTest(A, B, exact=FALSE)

```

SampleTwins

Sample Twins

Description

Draw a twin sample out of a population for a given recordset, by matching some strata criteria.

Usage

```

SampleTwins(x, stratanames = NULL, twins,
            method = c("srswor", "srswr", "poisson", "systematic"),
            pik, description = FALSE)

```

Arguments

x	the data to draw the sample from
stratanames	the stratanames to use
twins	the twin sample
method	method to select units; the following methods are implemented: simple random sampling without replacement (srswor), simple random sampling with replacement (srswr), Poisson sampling (poisson), systematic sampling (systematic); if "method" is missing, the default method is "srswor". See Strata .
pik	vector of inclusion probabilities or auxiliary information used to compute them; this argument is only used for unequal probability sampling (Poisson and systematic). If an auxiliary information is provided, the function uses the inclusion-probabilities function for computing these probabilities. If the method is "srswr" and the sample size is larger than the population size, this vector is normalized to one.
description	a message is printed if its value is TRUE; the message gives the number of selected units and the number of the units in the population. By default, the value is FALSE.

Value

The function produces an object, which contains the following information:

id	the identifier of the selected units.
stratum	the unit stratum.
prob	the final unit inclusion probability.

d.twin <- m[s$id,]
d.twin
```

SaveAsDlg

Save R Objects By Choosing a File Interactively

Description

SaveAsDlg displays the [file.choose](#) dialog to get a path/filename and uses [save](#) to write an external representation of R objects to the specified file

Usage

```
SaveAsDlg(x, filename)
```

Arguments

x	the name of the objects to be saved (as symbols or character strings).
filename	a (writable binary-mode) connection or the name of the file where the data will be saved (when tilde expansion is done). Must be a file name for save.image or version = 1. This is passed directly to the function save .

Author(s)

Andri Signorell <andri@signorell.net>

ScheffeTest

*Scheffe Test for Pairwise and Otherwise Comparisons***Description**

Scheffe's method applies to the set of estimates of all possible contrasts among the factor level means, not just the pairwise differences considered by Tukey's method.

Usage

```
ScheffeTest(x, ...)

## S3 method for class 'aov'
ScheffeTest(x, which = NULL, contrasts = NULL,
            conf.level = 0.95, ...)
## Default S3 method:
ScheffeTest(x, g = NULL, which = NULL,
            contrasts = NULL, conf.level = 0.95, ...)
```

Arguments

<code>x</code>	either a fitted model object, usually an <code>aov</code> fit, when <code>g</code> is left to <code>NULL</code> or a response variable to be evaluated by <code>g</code> (which mustn't be <code>NULL</code> then).
<code>g</code>	the grouping variable.
<code>which</code>	character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.
<code>contrasts</code>	a $r \times c$ matrix containing the contrasts to be computed, while r is the number of factor levels and c the number of contrasts. Each column must contain a full contrast ("sum") adding up to 0. Note that the argument <code>which</code> must be defined, when non default contrasts are used. Default value of <code>contrasts</code> is <code>NULL</code> . In this case all pairwise contrasts will be reported.
<code>conf.level</code>	numeric value between zero and one giving the confidence level to use. If this is set to <code>NA</code> , just a matrix with the p-values will be returned.
<code>...</code>	further arguments, currently not used.

Value

A list of classes `c("PostHocTest")`, with one component for each term requested in `which`. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr.ci` giving the lower end point of the interval, `upr.ci` giving the upper end point and `pval` giving the p-value after adjustment for the multiple comparisons.

There are print and plot methods for class `"PostHocTest"`. The plot method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.

```

SelectVarDlg

Select Elements of a Set by Click

Description

SelectVarDlg is a GUI utility, which brings up a dialog and lets the user select elements (either variables of a data.frame or levels of a factor) by point and click in a listbox. The list of selected items is written to the clipboard so that the code can afterwards easily be pasted in the source file.

Usage

```
SelectVarDlg(x, ...)

## Default S3 method:
SelectVarDlg(x, useIndex = FALSE, ...)

## S3 method for class 'factor'
SelectVarDlg(x, ...)
```

```
## S3 method for class 'data.frame'  
SelectVarDlg(x, ...)
```

Arguments

x	the object containing the elements to be selected. x can be a data.frame, a factor or any other vector.
useIndex	defines, if the enquoted names (default) or the index values should be returned.
...	further arguments to be passed to the default function.

Details

When working with big data.frames with many variables it is often tedious to build subsets by typing the columnnames. Here is where the function comes in offering a "point and click" approach for selecting the interesting columns. When x is a data.frame the columnnames are listed, when x is a factor the levels are listed and in all other cases the list is filled with the unique elements of x.

Value

A comma separated list with the selected values enquoted is returned invisibly as well as written to clipboard for easy inserting the text in an editor afterwards.

SelectVarDlg(x)  
  
## End(Not run)
```

SetAlpha

*Add an Alpha Channel To a Color***Description**

Add transparency to a color defined by its name or number. The function first converts the color to RGB and then appends the alpha channel.

Usage

```
SetAlpha(col, alpha = 0.5)
```

Arguments

col	vector of two kind of R colors, i.e., either a color name (an element of <code>colors()</code>) or an integer <code>i</code> meaning <code>palette()[i]</code> .
alpha	the alpha value to be added. This can be any value from 0 (fully transparent) to 1 (opaque). NA is interpreted so as to delete potentially Alpha channel. Default is 0.5.

Details

All arguments are recycled as necessary.

Value

Vector with the same length as `col`, giving the rgb-values extended by the alpha channel as hex-number (`#rrggbbaa`).

plot(x, type="p", col=SetAlpha("blue", .2), main="Better insight with alpha channel" )
```

ShapiroFranciaTest	<i>Shapiro-Francia test for normality</i>
--------------------	---

Description

Performs the Shapiro-Francia test for the composite hypothesis of normality.

Usage

```
ShapiroFranciaTest(x)
```

Arguments

<code>x</code>	a numeric vector of data values, the number of which must be between 5 and 5000. Missing values are allowed.
----------------	--

Details

The test statistic of the Shapiro-Francia test is simply the squared correlation between the ordered sample values and the (approximated) expected ordered quantiles from the standard normal distribution. The p-value is computed from the formula given by Royston (1993).

Value

A list with class “htest” containing the following components:

<code>statistic</code>	the value of the Shapiro-Francia statistic.
<code>p.value</code>	the p-value for the test.
<code>method</code>	the character string “Shapiro-Francia normality test”.
<code>data.name</code>	a character string giving the name(s) of the data.

Note

The Shapiro-Francia test is known to perform well, see also the comments by Royston (1993). The expected ordered quantiles from the standard normal distribution are approximated by `qnorm(ppoints(x, a = 3/8))`, being slightly different from the approximation `qnorm(ppoints(x, a = 1/2))` used for the normal quantile-quantile plot by [qqnorm](#) for sample sizes greater than 10.

```

SiegelTukeyTest	<i>Siegel-Tukey Test For Equality In Variability</i>
-----------------	--

Description

Non-parametric Siegel-Tukey test for equality in variability. The null hypothesis is that the variability of x is equal between two groups. A rejection of the null hypothesis indicates that variability differs between the two groups. SiegelTukeyRank returns the ranks, calculated after Siegel Tukey logic.

Usage

```
SiegelTukeyTest(x, ...)

## Default S3 method:
SiegelTukeyTest(x, y, adjust.median = FALSE,
                alternative = c("two.sided", "less", "greater"),
                mu = 0, exact = NULL, correct = TRUE, conf.int = FALSE,
                conf.level = 0.95, ...)

## S3 method for class 'formula'
SiegelTukeyTest(formula, data, subset, na.action, ...)

SiegelTukeyRank(x, g, drop.median = TRUE)
```

Arguments

x, y	numeric vector of data values. Non-finite (e.g. infinite or missing) values will be omitted.
adjust.median	Should between-group differences in medians be leveled before performing the test? In certain cases, the Siegel-Tukey test is susceptible to median differences and may indicate significant differences in variability that, in reality, stem from differences in medians.
alternative	a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
mu	a number specifying an optional parameter used to form the null hypothesis. See Details.

<code>exact</code>	a logical indicating whether an exact p-value should be computed. This is passed directly to <code>wilcox.test</code> .
<code>correct</code>	a logical indicating whether to apply continuity correction in the normal approximation for the p-value.
<code>conf.int</code>	a logical indicating whether a confidence interval should be computed.
<code>conf.level</code>	confidence level of the interval.
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>g</code>	a vector or factor object giving the group for the corresponding elements of <code>x</code> .
<code>drop.median</code>	logical, defining whether the median of the combined samples should be left out, ensuring that there's an even number of elements (which is a requirement of the Siegel-Tukey test). Defaults to <code>TRUE</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

The Siegel-Tukey test has relatively low power and may, under certain conditions, indicate significance due to differences in medians rather than differences in variabilities (consider using the argument `adjust.median`). Consider also using `mood.test` or `ansari.test`.

Value

A list of class `htest`, containing the following components:

<code>statistic</code>	Siegel-Tukey test (Wilcoxon test on tie-adjusted Siegel-Tukey ranks, after the median adjustment if specified).
<code>p.value</code>	the p-value for the test
<code>null.value</code>	is the value of the median specified by the null hypothesis. This equals the input argument <code>mu</code> .
<code>alternative</code>	a character string describing the alternative hypothesis.
<code>method</code>	the type of test applied
<code>data.name</code>	a character string giving the names of the data.

SignTest

*Sign Test***Description**

Performs one- and two-sample sign tests on vectors of data.

Usage

```

SignTest(x, ...)

## Default S3 method:
SignTest(x, y = NULL, alternative = c("two.sided", "less", "greater"),
         mu = 0, conf.level = 0.95, ...)

## S3 method for class 'formula'
SignTest(formula, data, subset, na.action, ...)

```

Arguments

<code>x</code>	numeric vector of data values. Non-finite (e.g. infinite or missing) values will be omitted.
<code>y</code>	an optional numeric vector of data values: as with <code>x</code> non-finite values will be omitted.
<code>mu</code>	a number specifying an optional parameter used to form the null hypothesis. See Details.
<code>alternative</code>	is a character string, one of "greater", "less", or "two.sided", or the initial letter of each, indicating the specification of the alternative hypothesis. For one-sample tests, <code>alternative</code> refers to the true median of the parent population in relation to the hypothesized value of the median.
<code>conf.level</code>	confidence level for the returned confidence interval, restricted to lie between zero and one.
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .

subset	an optional vector specifying a subset of observations to be used.
na.action	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
...	further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample test.

SignTest computes a “Dependent-samples Sign-Test” if both `x` and `y` are provided. If only `x` is provided, the “One-sample Sign-Test” will be computed.

For the one-sample sign-test, the null hypothesis is that the median of the population from which `x` is drawn is `mu`. For the two-sample dependent case, the null hypothesis is that the median for the differences of the populations from which `x` and `y` are drawn is `mu`. The alternative hypothesis indicates the direction of divergence of the population median for `x` from `mu` (i.e., “greater”, “less”, “two.sided”).

The confidence levels are exact.

Value

A list of class `htest`, containing the following components:

statistic	the S-statistic (the number of positive differences between the data and the hypothesized median), with names attribute “S”.
parameter	the total number of valid differences.
p.value	the p-value for the test.
null.value	is the value of the median specified by the null hypothesis. This equals the input argument <code>mu</code> .
alternative	a character string describing the alternative hypothesis.
method	the type of test applied.
data.name	a character string giving the names of the data.
conf.int	a confidence interval for the median.
estimate	the sample median.

```

Some numeric checks *Check a Vector For Being Numeric, Zero Or a Whole Number*

Description

Test if x contains only integer numbers, or if is numeric or if it is zero.

Usage

```

IsWhole(x, tol = .Machine$double.eps^0.5, na.rm = FALSE)
IsZero(x, tol = .Machine$double.eps^0.5, na.rm = FALSE)
IsNumeric(x, length.arg = Inf, integer.valued = FALSE, positive = FALSE, na.rm = FALSE)

```

Arguments

x a (non-empty) numeric vector of data values.

<code>tol</code>	tolerance to be used
<code>length.arg</code>	integer, the length of the vector to be checked for.
<code>integer.valued</code>	logical, should x be checked as integer?
<code>positive</code>	logical, is x supposed to be positive?
<code>na.rm</code>	logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.

Details

`IsWhole` is the suggested solution for checking for an integer value, as `is.integer` tests for `class(x) == "integer"` and does NOT test whether x (which might be of class "numeric") contains only integer numbers. (Why not simply implement it in **base**?)

`IsZero` tests float numeric values for being zero.

`IsNumeric` combines a test for numeric and integers.

Value

logical vector of the same dimension as x.

# These pagans expect ... (Burns, 2011)" the following to be TRUE:
(.1 - .3 / 3) == 0

# they might be helped by
IsZero(.1 - .3 / 3)
```

SomersDelta

Somers' Delta

Description

Calculate Somers' Delta statistic, a measure of association for ordinal factors in a two-way table. The function has interfaces for a table (matrix) and for single vectors.

Usage

```
SomersDelta(x, y = NULL, direction = c("row", "column"), conf.level = NA, ...)
```

Arguments

x a numeric vector or a table. A matrix will be treated as table.

y NULL (default) or a vector with compatible dimensions to x. If y is provided, `table(x, y, ...)` is calculated.

direction direction of the calculation. Can be "row" (default) or "column", where "row" calculates Somers' D (R | C) ("column dependent").

conf.level confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.

... further arguments are passed to the function `table`, allowing i.e. to set `useNA`. This refers only to the vector interface.

Details

Somers' D(C | R) and Somers' D(R | C) are asymmetric modifications of τ_b . C | R indicates that the row variable x is regarded as the independent variable and the column variable y is regarded as dependent. Similarly, R | C indicates that the column variable y is regarded as the independent variable and the row variable x is regarded as dependent.

Somers' D differs from tau-b in that it uses a correction only for pairs that are tied on the independent variable. Somers' D is appropriate only when both variables lie on an ordinal scale.

Somers' D is computed as

$$D(C|R) = \frac{P - Q}{n^2 - \sum (n_i.^2)}$$

where P equals twice the number of concordances and Q twice the number of discordances and $n_i.$ rowSums(tab). Its range lies [-1, 1].

Value

a single numeric value if no confidence intervals are requested
and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

```

Sort

Sort a Vector, a Matrix, a Table or a Data.frame

Description

Sort a vector, a matrix, a table or a data.frame. The base sort function does not have an interface for classes other than vectors and coerces the whole world to a vector. This means you get a sorted vector as result while passing a matrix to sort.

Sort wraps the base sort function and adds an interface for sorting the rows of the named 2-dimensional data structures by the order of one or more of its columns.

Usage

```
Sort(x, ...)
```

```
## Default S3 method:
Sort(x, ...)
## S3 method for class 'matrix'
Sort(x, ord = NULL, decreasing = FALSE, na.last = TRUE, ...)
## S3 method for class 'table'
Sort(x, ord = NULL, decreasing = FALSE, na.last = TRUE, ...)
## S3 method for class 'data.frame'
Sort(x, ord = NULL, decreasing = FALSE,
      factorsAsCharacter = TRUE, na.last = TRUE, ...)
```

Arguments

<code>x</code>	a numeric, complex, character or logical vector, a factor, a table or a data.frame to be sorted.
<code>decreasing</code>	logical. Should the sort be increasing or decreasing?
<code>factorsAsCharacter</code>	logical. Should factors be sorted by the alphabetic order of their labels or by the order of their levels. Default is TRUE (by labels).
<code>ord</code>	vector of integers or columnnames. Defines the columns in a table, in a matrix or in a data.frame to be sorted for. 0 means row.names, 1:n the columns and n+1 the marginal sum. See examples.
<code>na.last</code>	for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed (see order .)
<code>...</code>	further arguments to be passed to or from methods.

Details

The sort order for factors is the order of their levels (which is particularly appropriate for ordered factors), and usually confusing for unordered factors, whose levels may be defined in the sequence in which they appear in the data (which normally is unordered).

Value

the sorted object.

[sort](#), [order](#)

Examples

```
d.frm <- d.pizza[1:10, c("driver", "temperature", "delivery_min")]

Sort(d.frm[,1])
# Sort follows the levels by default
levels(d.frm[,1])

Sort(x=d.frm, ord="driver", decreasing=FALSE)
# set factorsAsCharacter = TRUE, if alphabetical order is required
Sort(x=d.frm, ord="driver", decreasing=FALSE, factorsAsCharacter=TRUE)

Sort(x=d.frm, ord=c("driver", "delivery_min"), factorsAsCharacter = TRUE)
Sort(x=d.frm, ord=c("driver", "delivery_min"), factorsAsCharacter = FALSE)

Sort(x=d.frm, ord=c("driver", "delivery_min"), decreasing=c(FALSE, TRUE),
     factorsAsCharacter = FALSE)

# Sorting tables
tab <- table(d.pizza$driver, d.pizza$area)
```

```
Sort(x=tab, ord=c(0,2), decreasing=c(TRUE, FALSE))
Sort(x=tab, ord=2, decreasing=TRUE)

# partial matching ok:
Sort(tab, o=1, d=TRUE)
```

SortMixed*Order or Sort Strings With Embedded Numbers So That The Numbers
Are In The Correct Order*

Description

These functions sort or order character strings containing numbers so that the numbers are numerically sorted rather than sorted by character value. I.e. "Asprin 50mg" will come before "Asprin 100mg". In addition, case of character strings is ignored so that "a", will come before "B" and "C".

Usage

```
SortMixed(x)
```

Arguments

x Character vector to be sorted

Details

I often have character vectors (e.g. factor labels) that contain both text and numeric data, such as compound and dose. This function is useful for sorting these character vectors into a logical order.

It does so by splitting each character vector into a sequence of character and numeric sections, and then sorting along these sections, with numbers being sorted by numeric value (e.g. "50" comes before "100"), followed by characters strings sorted by character value (e.g. "A" comes before "B").

Empty strings are always sorted to the front of the list, and NA values to the end.

Value

OrderMixed returns a vector giving the sort order of the input elements. SortMixed returns the sorted vector.

Author(s)

Gregory R. Warnes <greg@warnes.net>

See Also

[sort](#), [order](#)

Examples

```
# compound & dose labels
Treatment <- c("Control", "Asprin 10mg/day", "Asprin 50mg/day",
              "Asprin 100mg/day", "Acetomycin 100mg/day",
              "Acetomycin 1000mg/day")

# ordinary sort puts the dosages in the wrong order
sort(Treatment)

# but SortMixed does the 'right' thing
SortMixed(Treatment)

# Here is a more complex example
x <- rev(c("AA 0.50 ml", "AA 1.5 ml", "AA 500 ml", "AA 1500 ml",
          "EXP 1", "AA 1e3 ml", "A A A", "1 2 3 A", "NA", NA, "1e2",
          "", "-", "1A", "1 A", "100", "100A", "Inf"))

OrderMixed(x)

SortMixed(x)
# notice that plain numbers, including 'Inf' show up before strings.
```

SpearmanRho	<i>Spearman Rank Correlation</i>
-------------	----------------------------------

Description

Calculate Spearman correlation coefficient and it’s confidence interval.

Usage

```
SpearmanRho(x, y = NULL, use = c("everything", "all.obs", "complete.obs",
                                "na.or.complete", "pairwise.complete.obs"),
            conf.level = NA)
```

Arguments

x	a numeric vector, an ordered factor, matrix or data frame. An ordered factor will be coerced to numeric.
y	NULL (default) or a vector, an ordered factor, matrix or data frame with compatible dimensions to x. An ordered factor will be coerced to numeric.
use	an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".
conf.level	confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.

Details

The function calculates Spearman’s rho statistic by means of `cor(..., method="spearman")`. The confidence intervals are calculated via z-Transformation.

Value

Either a single numeric value, if no confidence interval is required,
or a vector with 3 elements for estimate, lower and upper confidence interval.

split.formula	<i>Formula Interface for Split</i>
---------------	------------------------------------

Description

Implementation of a simple formula interface for the [split](#) function.

Usage

```
## S3 method for class 'formula'
split(x, f, drop = FALSE, data = NULL, ...)
```

Arguments

x	a formula of the form $y \sim x$.
f	a 'factor' in the sense that as.factor (f) defines the grouping, or a list of such factors in which case their interaction is used for the grouping.
drop	logical indicating if levels that do not occur should be dropped (if f is a factor or a list). Defaults to FALSE.
data	the data frame from which the formula should be evaluated.
...	other arguments to be passed to split .

Examples

```
split(extra ~ group, data = sleep)
```

SplitPath	<i>Split Path In Drive, Path, Filename</i>
-----------	--

Description

Split a full path in its components.

Usage

```
SplitPath(path, last.is.file = NULL)
```

Arguments

path	a path
last.is.file	logical, determining if the basename should be interpreted as filename or as last directory. If set to NULL (default), the last entry will be interpreted if the last character is either \ or / and as filename else.

Value

A list, containing the following components:

normpath	the normalized path as returned by normalizePath
drive	the drive if the OS is Windows, a NULL string else
dirname	the path without directory and without filename
fullfilename	the filename including extension
filename	the filename without extension
extension	the file extension

path <- "C:/Documents/Projects/Import/eyestudy.dta"
SplitPath(path)

path <- "C:/Documents/Projects/Import/"
SplitPath(path)

path <- "C:/Documents/Projects/Import"
SplitPath(path) # last entry will be taken as filename
SplitPath(path, last.is.file=FALSE)
```

SpreadOut

*Spread Out a Vector of Numbers To a Minimum Interval***Description**

Spread out a vector of numbers so that there is a minimum interval between any two numbers when in ascending or descending order.

Usage

```
SpreadOut(x, mindist = NULL, cex = 1.0)
```

Arguments

x	a numeric vector which may contain NAs.
mindist	the minimum interval between any two values when in ascending or descending order. If this is left to NULL (default) the function will check if a plot is open and then use 90% of strheight .
cex	numeric character expansion factor; multiplied by <code>par("cex")</code> yields the final character size; the default NULL is equivalent to 1.

Details

SpreadOut starts at or near the middle of the vector and increases the intervals between the ordered values. NAs are preserved. SpreadOut first tries to spread groups of values with intervals less than mindist out neatly away from the mean of the group. If this doesn't entirely succeed, a second pass that forces values away from the middle is performed.

SpreadOut is currently used to avoid overplotting of axis tick labels where they may be close together.

Value

On success, the spread out values. If there are less than two valid values, the original vector is returned.

Note

This function is borrowed from the package **plotrix** (SpreadOut) and has been integrated here with some minor changes.

Author(s)

Jim Lemon <jim@bitwrit.com.au>
 some extensions Andri Signorell <andri@signorell>

Examples

```
SpreadOut(c(1, 3, 3, 3, 3, 5), 0.2)
SpreadOut(c(1, 2.5, 2.5, 3.5, 3.5, 5), 0.2)
SpreadOut(c(5, 2.5, 2.5, NA, 3.5, 1, 3.5, NA), 0.2)

# this will almost always invoke the brute force second pass
SpreadOut(rnorm(10), 0.5)
```

Stamp

Date/Time/Directory Stamp the Current Plot

Description

Date-time stamp the current plot in the extreme lower right corner. Optionally add the current working directory and arbitrary other text to the stamp.

Usage

```
Stamp(txt, pwd = FALSE, time = FALSE, srt = 0)
```

Arguments

txt	an optional single text string
pwd	set to TRUE to add the current working directory name to the stamp
time	set to FALSE to use the date without the time
srt	string rotation

Details

For R results may not be satisfactory if `par(mfrow=)` is in effect.

Author(s)

Frank E Harrell Jr <f.harrell@vanderbilt.edu>

Examples

```
plot(1:20)
Stamp(pwd=TRUE)
```

Str*Compactly Display the Structure of an Arbitrary R Object*

Description

Just a wrapper for [str](#) with the variables of a data.frame enumerated.

Usage

```
Str(x, ...)
```

Arguments

x	any R object about which you want to have some information.
...	all the dots are passed to str .

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[str](#)

Examples

```
Str(d.pizza)
```

StrAbbr*String Abbreviation*

Description

Abbreviate a character vector. The function includes starting from the first character as many characters as there are needed to result in a vector of unique values.

Usage

```
StrAbbr(x, minchar = 1, method = c("left", "fix"))
```

Arguments

x	character vector to be abbreviated
minchar	integer, minimal number of characters for the abbreviations.
method	one out of left or fix. While left restricts the result to as many characters are needed to ensure uniqueness, does fix yield a vector with all the elements being as long, as the the longest needed substring for differentiating the terms.

Value

The abbreviated strings.

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
StrAbbr(x=levels(d.pizza$driver), minchar=2)
StrAbbr(x=levels(d.pizza$driver), minchar=2, method="left")
StrAbbr(x=levels(d.pizza$driver), minchar=2, method="fix")

x <- c("Aaron", "Aaramis", "Berta", "Bello", "Claudia", "Cardinale", "Doretta", "Emilia")
StrAbbr(x, minchar=2, method="left")
StrAbbr(x, minchar=2, method="fix")
```

Strata	<i>Stratified sampling</i>
--------	----------------------------

Description

Stratified sampling with equal/unequal probabilities.

Usage

```
Strata(x, stratanames = NULL, size,
       method = c("srswor", "srswr", "poisson", "systematic"),
       pik, description = FALSE)
```

Arguments

x	a data frame or a matrix; its number of rows is n, the population size.
stratanames	vector of stratification variables.
size	vector of stratum sample sizes (in the order in which the strata are given in the input data set).
method	method to select units; implemented are: a) simple random sampling without replacement ("srswor"), b) simple random sampling with replacement ("srswr"), c) Poisson sampling ("poisson"), d) systematic sampling ("systematic") (default is "srswor").
pik	vector of inclusion probabilities or auxiliary information used to compute them; this argument is only used for unequal probability sampling (Poisson and systematic). If an auxiliary information is provided, the function uses the inclusion-probabilities function for computing these probabilities. If the method is "srswr" and the sample size is larger than the population size, this vector is normalized to one.

description a message is printed if its value is TRUE; the message gives the number of selected units and the number of the units in the population. By default, the value is FALSE.

Value

The function produces an object, which contains the following information:

id the identifier of the selected units.
 stratum the unit stratum.
 prob the final unit inclusion probability.

Author(s)

Andri Signorell <andri@signorell.net>

rewritten based on the ideas of Yves Tille <yves.tille@unine.ch> and Alina Matei <alina.matei@unine.ch>

```

StrCap*Capitalize the First Letter of a String*

Description

Capitalize the first letter of each element of the string vector.

Usage

```
StrCap(x)
```

Arguments

x String to be capitalized.

Value

Returns a vector of characters with the first letter capitalized

Author(s)

Charles Dupont <charles.dupont@vanderbilt.edu>

Examples

```
StrCap(c("Hello", "bob", "daN"))
```

StrChop*Split a String in a Number of Pieces With Fixed Length*

Description

Split a string in a number of pieces with fixed length

Usage

```
StrChop(x, len)
```

Arguments

x	the string to be cut in pieces.
len	a vector with the lengths of the pieces.

Details

If length is going over the end of the string the last part will be returned.

Value

a vector with the parts of the string.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[FixToTab](#)

Examples

```
x <- paste(letters, collapse="")
StrChop(x=x, len = c(3,5,2))
```

StrCountW*Count Words in a String*

Description

Count the number of words that appear within a character string.

Usage

```
StrCountW(x)
```

Arguments

x	a vector of strings to be parsed.
---	-----------------------------------

Details

This is just a wrapper for a fine regexp. It uses the expression `\b\W+\b` to separate the words. The code `\W` is equivalent to `[^[:alnum:]]` whereas `[:alnum:]` contains `[:alpha:]` and `[:digit:]`. So everything that is not an alphanumeric character, a digit or a `_` (underscore) is used as separator for the words to be counted.

Value

an integer defining the number of word in the string

Author(s)

Andri Signorell <andri@signorell.net>, based on code from Adam Bradley <hissself@adambradley.net>

References

<http://stackoverflow.com/questions/8920145/count-the-number-of-words-in-a-string-in-r>

[nchar](#)

Examples

```
StrCountW("This is a true story!")

StrCountW("Just_one_word")
StrCountW("Not-just.one/word")

StrCountW("And what about numbers 8899 or special characters $$$/*?")
StrCountW("  Starting\n ending with some whitespace ")

StrCountW(c("This is a", "text in more", "than one line."))
```

StrDist

Compute Distances Between Strings

Description

StrDist computes distances between strings following to Levenshtein or Hamming method.

Usage

```
StrDist(x, y, method = "levenshtein", mismatch = 1, gap = 1)
```

Arguments

<code>x</code>	character vector, first string.
<code>y</code>	character vector, second string.
<code>method</code>	character, name of the distance method. This must be "levenshtein" or "hamming". Default is the classical Levenshtein distance.
<code>mismatch</code>	numeric, distance value for a mismatch between symbols.
<code>gap</code>	numeric, distance value for inserting a gap.

Details

The function computes the Hamming and the Levenshtein (edit) distance of two given strings (sequences). The Hamming distance between two vectors is the number mismatches between corresponding entries.

In case of the Hamming distance the two strings must have the same length.

In case of the Levenshtein (edit) distance a scoring and a trace-back matrix are computed and are saved as attributes "ScoringMatrix" and "TraceBackMatrix". The numbers in the trace-back matrix reflect insertion of a gap in string y (1), match/mismatch (2), and insertion of a gap in string x (3).

Value

StrDist returns an object of class "dist"; cf. [dist](#).

Note

For distances between strings and for string alignments see also Bioconductor package **Biostrings**

## Hamming distance
StrDist(x, y, method="hamming")
```

StrIsNumeric

Does a String Contain Only Numeric Data

Description

Check whether a string does only contain numeric data.

Usage

```
StrIsNumeric(x)
```

Arguments

x a character vector

Value

a logical vector with the same dimension as x

Author(s)

Andri Signorell <andri@signorell.net>

See Also

Other string functions, e.g. [StrTrunc](#)

Examples

```
x <- c("123", "-3.141", "foobar123")
StrIsNumeric(x)
```

StrLeft, StrRight	<i>Returns the Left Part Or the Right Part Of a String</i>
-------------------	--

Description

Returns the left part or the right part Of a string.

Usage

```
StrLeft(x, n)
StrRight(x, n)
```

Arguments

x a vector of strings
n the number of characters to cut. n will be recycled.

Details

The function StrLeft is a simple wrapper to substr.

Value

the left (right) n characters of x

Author(s)

Andri Signorell <andri@signorell.net>

See Also[substr](#), [StrTrim](#)**Examples**

```
StrLeft("Hello world!", n=5)
StrRight("Hello world!", n=6)

StrLeft(c("Lorem", "ipsum", "dolor", "sit", "amet"), n=2)

StrRight(c("Lorem", "ipsum", "dolor", "sit", "amet"), n=c(2,3))
```

StrPad

*Pad a String With Justification***Description**

StrPad will fill a string x with defined characters to fit a given length.

Usage

```
StrPad(x, width, pad = " ", adj = "left")
```

Arguments

x	string to be padded.
width	resulting width of padded string.
pad	string to pad with. Will be repeated as often as necessary. Default is " ".
adj	adjustment of the old string, one of "left", "right", "center". If set to "left" the old string will be adjusted on the left and the new characters will be filled in on the right side.

Details

If a string x has more characters than width, it will be chopped on the length of width.

Value

the string

Author(s)

Christian W. Hoffmann <c-w.hoffmann@sunrise.ch>
some extensions Andri Signorell <andri@signorell.net>

Examples

```
StrPad("My string", 25, "XoX", "center")
# [1] "XoXXoXXoMy stringXXoXXoXX"
```

StrPos*Find Position of First Occurrence Of a String*

Description

This function finds the first occurrence of a substring within an object string.

Usage

```
StrPos(x, pattern, pos = 1, ...)
```

Arguments

x	a character vector in which to search for the pattern, or an object which can be coerced by <code>as.character</code> to a character vector.
pattern	character string (search string) containing the pattern to be matched in the given character vector. This can be a character string or a regular expression.
pos	pos allows, to define the start position for the search within x. The result will then be relativ to the begin of the truncated string. pos will be recycled.
...	the dots are passed to the function regexpr .

Details

Returns the numeric position of the first occurrence of needle in the haystack string. If the search string is not found, the result will be NA. This is just a wrapper for the function [regexpr](#).

Value

a vector of the first position of pattern in x

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[StrChop](#), [regexpr](#)

Examples

```
StrPos("t", levels(d.pizza$driver))
```

StrRev*Reverse a String*

Description

Returns a string in reverse order.

Usage

```
StrRev(x)
```

Arguments

x a string to be processed.

Value

string

Author(s)

Andri Signorell <andri@signorell.net>

See Also

String functions: [nchar](#), [match](#), [grep](#), [regexpr](#), [substr](#), [sub](#), [gsub](#), [StrTrunc](#), [StrDist](#)

Examples

```
StrRev("home")
StrRev("Anna")
```

StrTrim*Trim a string*

Description

The function removes all spaces, tabs and newlines from the beginning and end of the supplied string. If these whitespace characters occur in the middle of the string, they are preserved.

Trim with method "left" deletes only leading whitespaces, "right" only trailing. Designed for users who were socialized by SQL...

Usage

```
StrTrim(x, pattern = " \\t\\n", method = "both")
```

Arguments

x	the string to be trimmed.
pattern	the pattern of the whitespaces to be deleted, defaults to space, tab and newline: " \t\n".
method	one out of "both", "left", "right". Determines on which side the string should be trimmed. Default is "both".

Details

The functions are defined depending on method as

both: `gsub(pattern=gettextf("^[%s]+|[%s]+$", pattern, pattern), replacement="", x=x)`

left: `gsub(pattern=gettextf("^[%s]+", pattern), replacement="", x=x)`

right: `gsub(pattern=gettextf("[%s]+$", pattern), replacement="", x=x)`

Value

the string x without whitespaces

Author(s)

Andri Signorell <andri@signorell.net>

See Also

String functions: [nchar](#), [match](#), [grep](#), [regexpr](#), [substr](#), [sub](#), [gsub](#), [StrTrunc](#), [StrDist](#)

StrTrim(" Hello world! ", method="left")
StrTrim(" Hello world! ", method="right")

# user defined pattern
StrTrim(" ..Hello ... world! ", pattern=" \\.")
```

StrTrunc

Truncate Strings and Add Ellipses If a String is Truncated.

Description

Truncates one or more strings to a specified length, adding an ellipsis (...) to those strings that have been truncated. Use [formatC](#) to justify the strings if needed.

Usage

```
StrTrunc(x, maxlen = 20)
```

Arguments

x	a vector of strings.
maxlen	the maximum length of the returned strings.

Value

The string(s) passed as 'x' now with a maximum length of 'maxlen' + 3 (for the ellipsis).

Author(s)

Andri Signorell,
following an idea of Jim Lemon in `truncString()`

```
set.seed(1789)
x <- sapply(seq(10), function(x) paste(sample(letters, sample(20,1)),collapse=""))
x

StrTrunc(x, maxlen=10)

# right justification
formatC(StrTrunc(x, maxlen=10), width = 10, flag=" ")
```

StrVal

Extract All Numeric Values From a String

Description

Extract all numeric values from a string, using a regular expression and return a list of the values. If there are several, the values can be either be pasted and/or casted from character vectors to numeric values.

Usage

```
StrVal(x, paste = FALSE, as.numeric = FALSE)
```

Arguments

x	a character vector
paste	should separatetly extracted numbers be pasted together? This can be useful to reverse a prior format action. Default is FALSE.
as.numeric	logical value, determining if the extracted values should be converted to a number or be returned as characters. Default is FALSE.

Value

depending on the results the function will return either a character vector, in the case every element of x contained only one number, or a list of character vectors containing the found numbers.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

other string functions, e.g. [StrTrunc](#)

Examples

```
# a simple vector with only one number per element
StrVal(x=c("week 1", "week 3", "week 4", "week 5"))

# several numbers per element, extract each part, do not paste and return characters
StrVal(x=c("This is 1. place: 45.2", "none", "12.1 but -2.7 follow, 10.2e23 "),
       paste = FALSE, as.numeric = FALSE)

# a typical use case for this function is to reverse a previously
# applied number format

x <- c(100000, 4564654632, -456463)
xf <- Format(x, big.mark="'')

StrVal(xf, paste = TRUE, as.numeric = TRUE)

StrVal(xf, paste = TRUE, as.numeric = FALSE)
StrVal(xf, paste = FALSE, as.numeric = TRUE)
StrVal(xf, paste = FALSE, as.numeric = FALSE)
```

StuartMaxwellTest

Stuart-Maxwell Marginal Homogeneity Test

Description

This function computes the marginal homogeneity test for a $k \times k$ matrix of assignments of objects to k categories or an $n \times 2 \times k$ matrix of category scores for n data objects by two raters. The statistic is distributed as chi-square with k-1 degrees of freedom. It can be viewed as an extension of McNemar test to $k \times k$ table.

Usage

```
StuartMaxwellTest(x, y = NULL)
```

Arguments

x either a 2-way contingency table in matrix form, or a factor object.
y a factor object; ignored if x is a matrix.

Details

The null is that the probabilities of being classified into cells [i,j] and [j,i] are the same.

If x is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both x and y must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factors, and the contingency table is computed from these.

Value

A list with class "htest" containing the following components:

statistic	the value of the test statistic.
parameter	the degrees of freedom.
p.value	the p-value of the test.
method	a character string indicating what type of test was performed.
data.name	a character string giving the name of the data.

Author(s)

Andri Signorell <andri@signorell.net>, based on Code from Jim Lemon

StuartMaxwellTest(mc)
```

StuartTauC

Stuart τ_c

Description

Calculate Stuart's τ_c statistic, a measure of association for ordinal factors in a two-way table. The function has interfaces for a table (matrix) and for single vectors.

Usage

```
StuartTauC(x, y = NULL, conf.level = NA, ...)
```

Arguments

<code>x</code>	a numeric vector or a table. A matrix will be treated as table.
<code>y</code>	NULL (default) or a vector with compatible dimensions to <code>x</code> . If <code>y</code> is provided, <code>table(x, y, ...)</code> is calculated.
<code>conf.level</code>	confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
<code>...</code>	further arguments are passed to the function <code>table</code> , allowing i.e. to set <code>useNA</code> . This refers only to the vector interface.

Details

Stuart's τ_c makes an adjustment for table size in addition to a correction for ties. τ_c is appropriate only when both variables lie on an ordinal scale.

It is estimated by

$$\tau_c = \frac{m \cdot (P - Q)}{n^2 \cdot (m - 1)}$$

where P equals twice the number of concordances and Q twice the number of discordances, n is the total amount of observations and $m = \min(R, C)$. The range of τ_c is $[-1, 1]$.

See <http://support.sas.com/documentation/cdl/en/statugfreq/63124/PDF/default/statugfreq.pdf>, pp. 1739 for the estimation of the asymptotic variance.

Value

a single numeric value if no confidence intervals are requested,
and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

SysInfo

System Information And DescTools Options

Description

SysInfo is a convenience function to compile some information about the computing system and environment used.

Usage

```
SysInfo()
DescToolsOptions(default = FALSE)
```

Arguments

default logical, if set to TRUE the DescTools options will be reset to their default values.

Details

The function SysInfo is mainly used to save the system environment information in ncdf files containing the results of some calculations.

Options

There are a few options for the graphical output that can be set. DescToolsOptions displays the currently defined options.

1) Footnotes

In some tables there are footnote signs used. They're named footnote1, footnote2 and can be changed with e.g. options("footnote1"="*"). Any character can be defined here.

2) plotit

The option plotit can be used to make the Desc-procedures produce plots by default.

Set: options(plotit=TRUE). Valid values are TRUE and FALSE.

3) Colors

Three colors, that are used in many places can be set as options too. The options are col1, col2 and col3. By default they're set to hred, hblue and horange. Change the values by defining options(col1="pink", col2="blue", col2="yellow"). Any color definition can be used here.

Value

character string with all version and system information of the current R system

Author(s)

Jannis v. Buttlar <jbuttlar@bgc-jena.mpg.de>, Andri Signorell <andri@signorell.net>

TextContrastColor *Choose Textcolor Depending on Background Color*

Description

Text of a certain color when viewed against certain backgrounds can be hard to see. TextContrastColor returns either black or white depending on which has the better contrast.

Usage

```
TextContrastColor(col, method = c("glynn", "sonego"))
```

Arguments

col	vector of any of the three kind of R colors, i.e., either a color name (an element of colors()), a hexadecimal string of the form "#rrggbb" or "#rrggbbaa" (see rgb), or an integer i meaning palette()[i]. Non-string values are coerced to integer.
method	defines the algorithm to be used. Can be one out of "glynn" or "sonego". See details.

Details

A simple heuristic in defining a text color for a given background color, is to pick the one that is "farthest" away from "black" or "white". The way Glynn chooses to do this is to compute the color intensity, defined as the mean of the RGB triple, and pick "black" (intensity 0) for text color if the background intensity is greater than 127, or "white" (intensity 255) when the background intensity is less than or equal to 127. Sonego calculates $L \leftarrow c(0.2, 0.6, 0) \%*\% col2rgb(color)/255$ and returns #000060 if $L \geq 0.2$ and #FFFFFFA0 else.

Value

a vector containing the contrast color (either black or white)

Author(s)

Andri Signorell <andri@signorell.net> based on code of Earl F. Glynn, Stowers Institute for Medical Research, 2004

References

<http://research.stowers-institute.org/efg/R/Color/Chart>

Examples

```
# works fine for grays
PlotArea( y=matrix(rep(1, times=3, each=8), ncol=8), x=1:3,
  col=gray(1:8 / 8), ylab="", xlab="", axes=FALSE )
text( x=2, y=1:8-0.5, levels(d.pizza$driver),
  col=TextContrastColor(gray(1:8 / 8)))

# and not so fine, but still ok, for colors
```

```

par(mfrow=c(1,2))
PlotArea( y=matrix(rep(1, times=3, each=12), ncol=12), x=1:3,
  col=rainbow(12), ylab="", xlab="", axes=FALSE, main="method = Glynn" )
text( x=2, y=1:12-0.5, levels(d.pizza$driver),
  col=TextContrastColor(rainbow(12)))

PlotArea( y=matrix(rep(1, times=3, each=12), ncol=12), x=1:3,
  col=rainbow(12), ylab="", xlab="", axes=FALSE, main="method = Sonego" )
text( x=2, y=1:12-0.5, levels(d.pizza$driver),
  col=TextContrastColor(rainbow(12), method="sonego"))

```

TheilU

*Theil's U index of inequality***Description**

Calculate Theil's U index of inequality.

Usage

```
TheilU(a, p, type = c(2, 1), na.rm = FALSE)
```

Arguments

a	a numeric vector with the actual observed values.
p	a numeric vector containing the predictions.
type	defining the type of Theil's two U measures, see Details. Default is 2.
na.rm	logical, indicating whether NA values should be stripped before the computation proceeds. If set to TRUE complete cases of <code>cbind(x, y)</code> will be used. Defaults to FALSE.

Details

Theil proposed two error measures, but at different times and under the same symbol U, which has caused some confusion. U type = 1 is taken from Theil (1958, pp. 31-42). The argument a represents the actual observations and p the corresponding predictions. He left it open whether a and p should be used as absolute values or as observed and predicted changes.

Theil (1966, chapter 2) proposed U type = 2 as a measure of forecast quality: "...where A_i and P_i stand for a pair of predicted and observed changes. ..."

As U_1 has some serious disadvantages (see Bliemel 1973) it is recommended to use U_2 .

ToLong, ToWide

Reshape a Vector From Long to Wide Shape Or Vice Versa

Description

Simple reshaping a vector from long to wide or from wide to long shape by means of a single factor.

Usage

```
ToLong(x, varnames = NULL)
ToWide(x, g, varnames = NULL)
```

Arguments

x	the vector to be reshaped
g	the grouping vector to be used for the new columns.
varnames	the variable names if not the grouping levels should be used.

Details

ToLong expects x as a matrix or a data.frame and reshapes it to a factor representation. ToWide expects two vectors, x being the variable and g being the splitfactor.

Value

the reshaped object

Author(s)

Andri Signorell <andri@signorell.net>

See Also[reshape](#)**Examples**

```
d.x <- read.table(header=TRUE, text="
AA BB CC DD EE FF GG
7.9 18.1 13.3 6.2 9.3 8.3 10.6
9.8 14.0 13.6 7.9 2.9 9.1 13.0
6.4 17.4 16.0 10.9 8.6 11.7 17.5
")

ToLong(d.x)
```

Trim	<i>Trim a Vector</i>
------	----------------------

Description

Clean data by means of trimming, i.e., by omitting outlying observations.

Usage

```
Trim(x, trim = 0.1, na.rm = FALSE)
```

Arguments

x	a numeric vector to be trimmed.
trim	the fraction (0 to 0.5) of observations to be trimmed from each end of x before the mean is computed. Values of trim outside that range are taken as the nearest endpoint. The argument can also be set to an integer value. If trim is set to >1 it is interpreted as the number of elements to be cut off at each tail of x.
na.rm	a logical value indicating whether NA values should be stripped before the computation proceeds.

Details

A symmetrically trimmed vector x with a fraction of trim observations (resp. the given number) deleted from each end will be returned. If trim is set to a value >0.5 or to an integer value > n/2 then the result will be NA.

Value

The trimmed vector x. The result vector will be sorted (as [sort.int](#) is used within the function).

Note

This function is basically an excerpt from the base function [mean](#), which allows the vector x to be trimmed before calculating the mean. But what if a trimmed sd is needed?

Author(s)

R-Core (function mean), Andri Signorell <andri@signorell.net>

[Winsorize](#)

Examples

```
## generate data
set.seed(1234)      # for reproducibility
x <- rnorm(10)      # standard normal
x[1] <- x[1] * 10    # introduce outlier

## Trim data
x
Trim(x, trim=0.1)

## Trim fixed number, say cut the 3 extreme elements from each end
Trim(x, trim=3)
```

TukeyBiweight

Calculate Tukey's Biweight Robust Mean

Description

This calculates a robust average that is unaffected by outliers.

Usage

```
TukeyBiweight(x, const = 9, na.rm = FALSE,
              conf.level = NA, ci.type = "bca", R=1000, ...)
```

Arguments

<code>x</code>	a numeric vector
<code>const</code>	a constant. <i>const</i> is preassigned a value of 9 according to the Cook reference below but other values are possible.
<code>na.rm</code>	logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.
<code>conf.level</code>	confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
<code>ci.type</code>	The type of confidence interval required. The value should be any subset of the values "basic", "stud", "perc", "bca" or simply "all" which will compute all four types of intervals.
<code>R</code>	The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case R would be a vector of integers where each component gives the number of resamples from each of the rows of weights.
<code>...</code>	the dots are passed to the function boot , when confidence intervals are calculated.

Details

This is a one step computation that follows the Affy whitepaper below, see page 22. *const* determines the point at which outliers are given a weight of 0 and therefore do not contribute to the calculation of the mean. *const* = 9 sets values roughly +/-6 standard deviations to 0. *const* = 6 is also used in tree-ring chronology development. Cook and Kairiukstis (1990) have further details.

An exact summation algorithm (Shewchuk 1997) is used. When some assumptions about the rounding of floating point numbers and conservative compiler optimizations hold, summation error is completely avoided. Whether the assumptions hold depends on the platform, i.e. compiler and CPU.

Value

A numeric mean.

Author(s)

Mikko Korpela <mikko.korpela@aalto.fi>

UncertCoef

Uncertainty Coefficient

Description

The uncertainty coefficient $U(C|R)$ measures the proportion of uncertainty (entropy) in the column variable Y that is explained by the row variable X . The function has interfaces for a table, a matrix, a data.frame and for single vectors.

Usage

```
UncertCoef(x, y = NULL, direction = c("symmetric", "row", "column"),
  conf.level = NA, p.zero.correction = 1/sum(x)^2, ...)
```

Arguments

<code>x</code>	a numeric vector, a factor, matrix or data frame.
<code>y</code>	NULL (default) or a vector, an ordered factor, matrix or data frame with compatible dimensions to <code>x</code> .
<code>direction</code>	direction of the calculation. Can be "row" (default) or "column", where "row" calculates UncertCoef (RIC) ("column dependent").
<code>conf.level</code>	confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
<code>p.zero.correction</code>	slightly nudge zero values so that their logarithm can be calculated
<code>...</code>	further arguments are passed to the function table , allowing i.e. to set useNA. This refers only to the vector interface.

Details

The uncertainty coefficient is computed as

$$U(C|R) = \frac{H(X) + H(Y) - H(XY)}{H(Y)}$$

and ranges from [0, 1].

Value

Either a single numeric value, if no confidence interval is required,
or a vector with 3 elements for estimate, lower and upper confidence interval.

Author(s)

Andri Signorell <andri@signorell.net> strongly based on code from Antti Arppe <antti.arppe@helsinki.fi>

UnitConv	<i>Unit Conversion</i>
----------	------------------------

Description

Convert a number from one measurement system to another. The function can translate a table of distances in miles to a table of distances in kilometers.

Usage

```
UnitConv(x, from_unit, to_unit)

data(d.units)
data(d.prefix)
```

Arguments

- x the numeric to be converted.
- from_unit a character defining the original unit.
- to_unit a character defining the target unit.

Details

The following units can be chosen. Conversions will work with units within the group. NA wil be returned if a conversion can't be found.
The multipliers can be found in the dataset d.units.

Untable	<i>Recover Original Data From Contingency Table</i>
---------	---

Description

Recreates the data.frame out of a contingency table x.

Usage

```
Untable(x, ...)

## S3 method for class 'data.frame'
Untable(x, freq = "Freq", rownames = NULL, ...)
## Default S3 method:
Untable(x, dimnames = NULL, type = NULL, rownames = NULL, colnames = NULL, ...)
```

Arguments

x	a numeric vector, a matrix, a table or a data.frame. If x is a vector, a matrix or a table it is interpreted as frequencies which are to be inflated to the original list. If x is a data.frame it is interpreted as a table in frequency form (containing one or more factors and a frequency variable).
dimnames	the dimension names of x to be used for expanding. Can be used to expand a weight vector to its original values. If set to NULL (default) the dimnames of x will be used.
type	defines the data type generated. This allows to directly define factors or ordered factors, but also numeric values. See examples.
rownames	A names vector for the rownames of the resulting data.frame. If set to NULL (default) the names will be defined according to the table's dimnames.
colnames	A names vector for the colnames of the resulting data.frame. If set to NULL (default) the names will be defined according to the table's dimnames.
freq	character, the name of the frequency variable in case x is a data.frame.
...	further arguments passed to or from functions (not used here).

Details

For x being a vector this reduces to `rep(..., n)` with n as vector (which is not supported by rep).

Value

a data.frame with the detailed data (even if x was a 1-dimensional table)

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[expand.grid](#), [rep](#), [gl](#), [xtabs](#)

Examples

```
d.titanic <- Untable(Titanic)
str(d.titanic)

# ... not the same as:
data.frame(Titanic)

tab <- table(set1=sample(letters[1:5], size=40, replace=TRUE),
             set2=sample(letters[11:15], size=40, replace=TRUE))
Untable(tab)

# return a numeric vector by setting type and coerce to a vector by [,]
Untable(c(6,2,2), type="as.numeric")[,]

# how to produce the original list based on frequencies, given as a data.frame
d.freq <- data.frame(xtabs(Freq ~ Sex + Survived, data=Titanic))

# a data list with each individual
d.data <- Untable( xtabs(c(1364, 126, 367, 344) ~ .,
                       expand.grid(levels(d.freq$Sex), levels(d.freq$Survived))))
head(d.data)

# expand a weights vector
Untable(c(1,4,5), dimnames=list(c("Zurich", "Berlin", "London"))))

# and the same with a numeric vector
Untable(c(1,4,5), dimnames=list(c(5,10,15)), type="as.numeric")[,]
# ... which again is nothing else than
rep(times=c(1,4,5), x=c(5,10,15))

# the data.frame interface
d.freq <- data.frame(f1=c("A", "A", "B", "B"), f2=c("C", "D", "C", "D"), Freq=c(1,2,3,4))
Untable(d.freq)
```

Description

Calculates the confidence interval for the variance either the classical way or with the bootstrap approach.

Usage

```
VarCI(x, method = c("classic", "norm", "basic", "stud", "perc", "bca"),
      conf.level = 0.95, na.rm = FALSE, R = 999)
```

Arguments

<code>x</code>	a (non-empty) numeric vector of data values.
<code>method</code>	A vector of character strings representing the type of intervals required. The value should be any subset of the values "classic", "norm", "basic", "stud", "perc", "bca". See boot.ci .
<code>conf.level</code>	confidence level of the interval.
<code>na.rm</code>	logical. Should missing values be removed? Defaults to FALSE.
<code>R</code>	The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case <code>R</code> would be a vector of integers where each component gives the number of resamples from each of the rows of weights. See boot .

Value

a numeric vector with 3 elements:

<code>var</code>	variance
<code>lwr.ci</code>	lower bound of the confidence interval
<code>upr.ci</code>	upper bound of the confidence interval

Author(s)

Andri Signorell <andri@signorell.net>

```

VecRot*Vector Rotation*

Description

Shift the elements of a vector in circular mode to the right or to the left by *n* elements, such that the *n*th element is the first one of the new vector and the first *n*-1 elements are appended to the end.

Usage

```
VecRot(x, n)
```

Arguments

<i>x</i>	a vector of any type.
<i>n</i>	the number of elements to shift.

Details

The function will repeat the vector two times and select the appropriate number of elements from the required shift on.

Value

the shifted vector in the same dimensions as *x*.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[\[, rep](#)

Examples

```
VecRot(c(1,1,0,0,3,4,8), 3)

VecRot(letters[1:10], 3)
```

Vigenere	<i>Vigenere Cypher</i>
----------	------------------------

Description

Implements a Vigenere cypher, both encryption and decryption. The function handle keys and text of unequal length and discards non-alphabetic characters.

Usage

```
Vigenere(x, key = NULL, decrypt = FALSE)
```

Arguments

x	the text to be encrypted
key	the key to be used. If this remains to NULL the PasswordDlg will be presented and the key can be entered there.
decrypt	boolean defining if the text should be encrypted or decrypted.

Details

All characters beside charlist = c(LETTERS, letters, 0:9) will be discarded from the text and from the key.

Value

the encrypted, resp. decrypted text

Author(s)

Andri Signorell <andri@signorell.net>
strongly based on code found at http://rosettacode.org/wiki/Vigen%C3%A8re_cipher#R (credits to the unknown soldier)

Examples

```
key <- "My FavoriteKey452"  
(xenc <- Vigenere("Beware the Jabberwock, my son! The jaws that bite, the claws that catch!", key))  
  
Vigenere(xenc, key, decrypt = TRUE)  
# note that everything besides the characters in the list will be discarded
```

wdConst	<i>Word VBA constants</i>
---------	---------------------------

Description

This is a list with all VBA constants for MS Word 2010, which is useful for writing R functions based on recorded macros in Word. This way the constants need not be replaced by their numeric values and can only be complemented with the list's name, say the VBA-constant wd10Percent for example can be replaced by wdConst\$wd10Percent.

Usage

```
data(wdConst)
```

Format

The format is:
 List of 2755
 \$ wd100Words: num -4
 \$ wd10Percent: num -6
 \$ wd10Sentences: num -2
 ...

Source

Microsoft

Winsorize	<i>Winsorize</i>
-----------	------------------

Description

Clean data by means of winsorization, i.e., by shrinking outlying observations to the border of the main part of the data.

Usage

```
Winsorize(x, minval = quantile(x = x, probs = probs[1], na.rm = na.rm),
          maxval = quantile(x = x, probs = probs[2], na.rm = na.rm),
          probs = c(0.05, 0.95), na.rm = FALSE)
```

Arguments

x	a numeric vector to be winsorized.
minval	the low border, all values being lower than this will be replaced by this value. The default is set to the 5%-quantile of x.
maxval	the high border, all values being larger than this will be replaced by this value. The default is set to the 95%-quantile of x.

probs numeric vector of probabilities with values in [0,1] as used in [quantile](#).
na.rm should NAs be omitted to calculate the quantiles?
Note that NAs in x are preserved and left unchanged anyway.

Details

Consider standardizing (possibly robust) the data before winsorizing. See [scale](#), [RobScale](#)

Value

A vector of the same length as the original data x containing the winsorized data.

Author(s)

Andri Signorell <andri@signorell.net>, based on code by Gabor Grothendieck <ggrothendieck@gmail.com>

See Also

[Winsorize](#) library(robustHD) contains an option to winsorize multivariate data

Examples

```
## generate data
set.seed(1234)      # for reproducibility
x <- rnorm(10)      # standard normal
x[1] <- x[1] * 10    # introduce outlier

## Winsorize data
x
Winsorize(x)

# use Large and Small, if a fix number of values should be winsorized (here k=3):
Winsorize(x, minval=tail(Small(x, k=3), 1), maxval=head(Large(x, k=3), 1))
```

WoolfTest

Woolf Test

Description

Test for homogeneity on $2 \times 2 \times k$ tables over strata (i.e., whether the log odds ratios are the same in all strata).

Usage

```
WoolfTest(x)
```

Arguments

x a $2 \times 2 \times k$ table.

Value

A list of class "htest" containing the following components:

statistic	the chi-squared test statistic.
parameter	degrees of freedom of the approximate chi-squared distribution of the test statistic.
p.value	<i>p</i> -value for the test.
method	a character string indicating the type of test performed.
data.name	a character string giving the name(s) of the data.
observed	the observed counts.
expected	the expected counts under the null hypothesis.

Note

This function was previously published as `woolf_test()` in the **vcd** package and has been integrated here without logical changes.

                      freq=c(16, 5, 11, 20, 12, 7, 16, 19))
                  )

WoolfTest(migraine)
```

WrdCaption	<i>Insert Caption to Word</i>
------------	-------------------------------

Description

Insert a caption in a given level to a Word document. The caption is inserted at the current cursor position.

Usage

```
WrdCaption(x, stylename = wdConst$wdStyleHeading1, wrd = getOption("lastWord"))
```

Arguments

x	the text of the caption.
stylename	the name of the heading style in local language or the appropriate word constant.
wrd	the pointer to a word instance. Can be a new one, created by <code>GetNewWrd()</code> or an existing one, created by <code>GetCurrWrd()</code> . Default is the last created pointer stored in <code>getOption("lastWord")</code> .

Author(s)

Andri Signorell <andri@signorell.net>

)

## End(Not run)
```

WrdInsertBookmark	<i>Insert a Bookmark, Goto Bookmark and Update the Text of a Bookmark</i>
-------------------	---

Description

WrdInsertBookmark inserts a new bookmark in a Word document. WrdGotoBookmark allows to set the cursor on the bookmark and WrdUpdateBookmark sets the text within the range of the bookmark.

Usage

```
WrdInsertBookmark(name, wrd = getOption("lastWord"))
WrdGoto(name, what = wdConst$wdGoToBookmark, wrd = getOption("lastWord"))

WrdUpdateBookmark(name, text, what = wdConst$wdGoToBookmark, wrd = getOption("lastWord"))
```

Arguments

name	the name of the bookmark.
text	the text of the bookmark.
what	a word constant, defining the type of object to be used to place the cursor.
wrd	the pointer to a word instance. Can be a new one, created by <code>GetNewWrd()</code> or an existing one, created by <code>GetCurrWrd()</code> . Default is the last created pointer stored in <code>getOption("lastWord")</code> .

Details

Bookmarks are useful to build structured documents, which can be updated later.

## End(Not run)
```

WrdInsTab	<i>Insert a Table in a Word Document</i>
-----------	--

Description

Create a table with a specified number of rows and columns in a Word document at the current position of the cursor.

Usage

```
WrdInsTab(nrow = 1, ncol = 1, heights = NULL, widths = NULL, main = NULL,
          wrd = getOption("lastWord"))
```

Arguments

nrow	number of rows.
ncol	number of columns.
heights	a vector of the row heights (in [cm]). If set to NULL (which is the default) the Word defaults will be used. The values will be recycled, if necessary.
widths	a vector of the column widths (in [cm]). If set to NULL (which is the default) the Word defaults will be used. The values will be recycled, if necessary.
main	a caption for the plot. This will be inserted by InsertCaption in Word. Default is NULL, which will insert nothing.
wrd	the pointer to a word instance. Can be a new one, created by GetNewWrd() or an existing one, created by GetCurrWrd(). Default is the last created pointer stored in getOption("lastWord").

Value

A pointer to the inserted table.

## End(Not run)
```

WrdPlot

Insert Active Plot to Word

Description

This function inserts the plot on the active plot device to Word. The image is transferred by saving the picture to a file in R and inserting the file in Word. The format of the plot can be selected, as well as crop options and the size factor for inserting.

Usage

```
WrdPlot(type = "png", append.cr = TRUE, crop = c(0, 0, 0, 0), main = NULL,
        picscale = 100, height = NA, width = NA, res = 300,
        dfact = 1.6, wrd = getOption("lastWord"))
```

Arguments

<code>type</code>	the format for the picture file, default is "png".
<code>append.cr</code>	should a carriage return be appended? Default is TRUE.
<code>crop</code>	crop options for the picture, defined by a 4-elements-vector. The first element is the bottom side, the second the left and so on.
<code>main</code>	a caption for the plot. This will be inserted by <code>InserCaption</code> in Word. Default is NULL, which will insert nothing.
<code>picscale</code>	scale factor of the picture in percent, default is 100.
<code>height</code>	height in cm, this overrides the <code>picscale</code> if both are given.
<code>width</code>	width in cm, this overrides the <code>picscale</code> if both are given.
<code>res</code>	resolution for the png file, defaults to 300.
<code>dfact</code>	the size factor for the graphic.
<code>wrd</code>	the pointer to a word instance. Can be a new one, created by <code>GetNewWrd()</code> or an existing one, created by <code>GetCurrWrd()</code> . Default is the last created pointer stored in <code>getOption("lastWord")</code> .

Value

Returns a pointer to the inserted picture.

## End(Not run)
```

WrdR*Insert a R Command and It's Output in a Word Document*

Description

Insert an R Command and It's Output in Word document. Helpful for documenting tasks.

Usage

```
WrdR(x, wrđ = getOption("lastWord"))
```

Arguments

x	R command as text to be evaluated.
wrd	the pointer to a word instance. Can be a new one, created by <code>GetNewWrd()</code> or an existing one, created by <code>GetCurrWrd()</code> . Default is the last created pointer stored in <code>getOption("lastWord")</code> .

Details

The command text will be placed in a Word document and formatted in italics. The result will be written in bold fontface.

WrdSetFont	<i>Set the Font in Word</i>
------------	-----------------------------

Description

WrdSetFont sets the font in Word for the text to be inserted. WrdGetFont returns the font at the current cursor position.

Usage

```
WrdSetFont(fontname = "Consolas", fontsize = 7, bold = FALSE, italic = FALSE,
           wrd = getOption("lastWord"))
WrdGetFont(wrd = getOption("lastWord"))
```

Arguments

fontname	the name of the font as defined by Windows.
fontsize	the size of the font in points.
bold, italic	does the expected.
wrd	the pointer to a word instance. Can be a new one, created by GetNewWrd() or an existing one, created by GetCurrWrd(). Default is the last created pointer stored in getOption("lastWord").

Value

a list of the attributes of the font in the current cursor position:

name	the fontname
size	the fontsize
bold	bold
italic	italic

Examples

```
## Not run: # Windows-specific example
# start word
wrd <- GetNewWrd()

for( i in seq(10, 24, 2)) {
  WrdText(gettextf("This is Arial size %s \n", i), appendCR=FALSE,
          fontname="Arial", fontsize=i)
}
for( i in seq(10, 24, 2)) {
```

```

    WrdText(gettextf("This is Times size %s \n", i), appendCR=FALSE,
            fontname="Times", fontsize=i)
}

## End(Not run)

```

WrdTable

Produces a Table in Word

Description

Creates a table in MS-Word.

Usage

```

WrdTable(tab, main = NULL, wrd = getOption("lastWord"), row.names = FALSE, ...)

## S3 method for class 'Freq'
WrdTable(tab, main = NULL, wrd = getOption("lastWord"), row.names = FALSE, ...)

## S3 method for class 'ftable'
WrdTable(tab, main = NULL, wrd = getOption("lastWord"), row.names = FALSE, ...)

## Default S3 method:
WrdTable(tab, main = NULL, wrd = getOption("lastWord"), row.names = FALSE,
         fmt = NULL, fontsize = NULL,...)

```

Arguments

tab	the table to be transferred to Word.
main	a caption for the plot. This will be inserted by InsertCaption in Word. Default is NULL, which will insert nothing.
wrd	the pointer to a word instance. Can be a new one, created by GetNewWrd() or an existing one, created by GetCurrWrd(). Default is the last created pointer stored in getOption("lastWord").
row.names	logical, defining whether rownames should be included in the output or not. Default is FALSE.
fmt	format string for the table giving the alignment in the columns. l means left, r right and c center alignment. The format code will be recycled.
fontsize	the fontsize of the table
...	further arguments to be passed to or from methods.

Details

A tricky problem, still unsolved... This is experimental code.

WrdText	<i>Insert Normal Text to Word</i>
---------	-----------------------------------

Description

Write text in defined font and append a carriage return if requested.

Usage

```
WrdText(txt, fixedfont = TRUE, fontname = NULL, fontsize = NULL,
        bold = FALSE, italic = FALSE, col = NULL,
        alignment = c("left","right","center"), spaceBefore=0, spaceAfter=0,
        lineSpacingRule = wdConst$wdLineSpaceSingle,
        appendCR = TRUE, wrd = getOption("lastWord"))
```

Arguments

txt	the text to be inserted.
fixedfont	should a fixedfont be used. Default is TRUE.
fontname	the font of the text. If left to NULL the fixedfont will be used, and if the option does not exist it will be set to Consolas.
fontsize	the fontsize of the text. If left to NULL the fixedfontsize will be used, and if the option does not exist it will be set to 7.
bold	should the text be bold?
italic	should the text be italic?
col	the text color, defaults to black.
alignment	alignment of the paragraph, can be one out of left, right, center
spaceBefore	space before the paragraph in pts as set in Word.
spaceAfter	space after the paragraph in pts as set in Word.
lineSpacingRule	spacing in pts
appendCR	should a carriage return be appended to the text. Default is TRUE.
wrd	the pointer to a word instance. Can be a new one, created by GetNewWrd() or an existing one, created by GetCurrWrd(). Default is the last created pointer stored in getOption("lastWord").

Value

Returns a list of the attributes of the font in the current cursor position.

name	the fontname
size	the fontsize
bold	bold
italic	italic

## End(Not run)

```

XLGetRange

Import Data Directly From Excel

Description

The package RDCOMClient is used to open an Excel workbook and return the content (value) of one (or several) given range(s) in a specified sheet. Helpful, if pathologically scattered data on an Excel sheet, which can't simply be saved as CSV-file, has to be imported in R.

XLGetWorkbook does the same for all the sheets in an Excel workbook.

Usage

```

XLGetRange(file = NULL, sheet = NULL, range = NULL, as.data.frame = TRUE,
            header = FALSE, stringsAsFactors = FALSE)

```

```

XLGetWorkbook(file)

```

Arguments

file	the fully specified path and filename of the workbook. If it is left as NULL, the function will look for a running Excel-Application and use its current sheet. The parameter sheet will be ignored in this case.
sheet	the name of the sheet containing the range(s) of interest.
range	a scalar or a vector with the address(es) of the range(s) to be returned (characters). Use "A1"-address mode to specify the ranges, for example "A1:F10".

	If set to NULL (which is the default), the function will look for a selection that contains more than one cell. If found, the function will use this selection. If there is no selection then the current region of the selected cell will be used.
<code>as.data.frame</code>	logical. Determines if the cellranges should be coerced into data.frames. Defaults to TRUE, as this is probably the common use of this function.
<code>header</code>	a logical value indicating whether the range contains the names of the variables as its first line. Default is FALSE. header is ignored if <code>as.data.frame</code> has been set to FALSE.
<code>stringsAsFactors</code>	logical. Should character columns be coerced to factors? The default is FALSE, which will return character vectors.

Details

The result consists of a list of lists, if `as.data.frame` is set to FALSE. Be then prepared to encounter NULL values. Those will prevent from easily being able to coerce the square data structure to a data.frame.

The following code will replace the NULL values by NA and coerce the data to a data.frame.

```
# get the range D1:J69 from an excel file
xlrng <- XLGetRange(file="myfile.xlsx", sheet="Tabelle1",
  range="D1:J69", as.data.frame=FALSE)

# replace NULL values by NA
xlrng[unlist(lapply(xlrng, is.null))] <- NA

# coerce the square data structure to a data.frame
d.lka <- data.frame(lapply(data.frame(xlrng), unlist))
```

This of course can be avoided by setting `as.data.frame = TRUE`.

The function will return dates as integer values, because XL stores them as integers. An Excel date can be converted with the (unusual) origin of `as.Date(myDate, origin="1899-12-30")`.

Value

If `as.data.frame` is set to TRUE, a single data.frame or a list of data.frames will be returned. If set to FALSE a list of the cell values in the specified Excel range, resp. a list of lists will be returned.

XLGetWorkbook returns a list of lists of the values in the given workbook.

# if the current region is to be read (inkl. a header), place the cursor in the interesting region
# and run:
d.set <- XLGetRange(header=TRUE)

## End(Not run)
```

XLView

Use Excel as Viewer for a Data.Frame

Description

XLView can be used to view and edit a data.frame directly in Excel, resp. to create a new data.frame in Excel.

Usage

```
XLView(x, col.names = TRUE, row.names = TRUE)

XLKill()
```

Arguments

x	is a data.frame to be transferred to Excel. If data is missing a new file will be created.
row.names	either a logical value indicating whether the row names of x are to be written along with x, or a character vector of row names to be written.
col.names	either a logical value indicating whether the column names of x are to be written along with x, or a character vector of column names to be written. See the section on 'CSV files' write.table for the meaning of col.names = NA.

Details

The data.frame will be exported in CSV format and then imported in Excel. Take care: Changes to the data made in Excel will NOT automatically be updated in the original data.frame. The user will have to read the csv-file into R again. See examples how to get this done.

XLKill will kill a running XL instance (which might be invisible). Background is the fact, that the simple XL\$quit() command would not terminate a running XL task, but only set it invisible (observe the TaskManager). This ghost version may sometimes confuse XLView and hinder to create a new instance. In such cases you have to do the garbage collection...

Value

the name/path of the temporary file edited in Excel.

Note

The function works only in Windows and requires **RDCOMClient** to be installed (see: Additional_repositories in DESCRIPTION of the package).

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
## Not run: # Windows-specific example
XLView(d.diamonds)

# edit an existing data.frame in Excel, make changes and save there, return the filename
fn <- XLView(d.diamonds)
# read the changed file and store in new data.frame
d.frm <- read.table(fn, header=TRUE, quote="", sep=";")

# Create a new file, edit it in Excel...
fn <- XLView()
# ... and read it into a data.frame when in R again
d.set <- read.table(fn, header=TRUE, quote="", sep=";")

# Export a ftable object, quite elegant...
XLView(format(ftable(Titanic), quote=FALSE), row.names = FALSE, col.names = FALSE)

## End(Not run)
```

YuenTTest

Yuen t-Test For Trimmed Means

Description

Performs one and two sample Yuen t-tests for trimmed means on vectors of data.

Usage

```
YuenTTest(x, ...)
```

Default S3 method:

```
YuenTTest(x, y = NULL, alternative = c("two.sided", "less", "greater"),
          mu = 0, paired = FALSE, conf.level = 0.95, trim = 0.2, ... )
```

S3 method for class 'formula'

```
YuenTTest(formula, data, subset, na.action, ...)
```

Arguments

<code>x</code>	numeric vector of data values. Non-finite (e.g. infinite or missing) values will be omitted.
<code>y</code>	an optional numeric vector of data values: as with <code>x</code> non-finite values will be omitted.
<code>alternative</code>	is a character string, one of "greater", "less", or "two.sided", or the initial letter of each, indicating the specification of the alternative hypothesis. For one-sample tests, <code>alternative</code> refers to the true median of the parent population in relation to the hypothesized value of the mean.
<code>paired</code>	a logical indicating whether you want a paired z-test.
<code>mu</code>	a number specifying the hypothesized mean of the population.
<code>conf.level</code>	confidence level for the interval computation.
<code>trim</code>	the fraction (0 to 0.5) of observations to be trimmed from each end of <code>x</code> before the mean is computed. Values of <code>trim</code> outside that range are taken as the nearest endpoint.
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Value

An object of class `htest` containing the following components:

<code>statistic</code>	the value of the t-statistic.
<code>parameter</code>	the degrees of freedom for the t-statistic and the trim percentage used.
<code>p.value</code>	the p-value for the test.
<code>conf.int</code>	a confidence interval for the trimmed mean appropriate to the specified alternative hypothesis.
<code>estimate</code>	the estimated trimmed mean or difference in trimmed means depending on whether it was a one-sample test or a two-sample test.
<code>null.value</code>	the specified hypothesized value of the trimmed mean or trimmed mean difference depending on whether it was a one-sample test or a two-sample test.
<code>alternative</code>	a character string describing the alternative hypothesis.
<code>method</code>	a character string indicating what type of test was performed.
<code>data.name</code>	a character string giving the name(s) of the data.

with(d.oxen, YuenTTest(int, ext, paired=FALSE))
```

ZeroIfNA

Replace NAs by 0

Description

Replace NAs in a vector x with 0. This function has the same logic as the zeroifnull function in SQL.

Usage

```
ZeroIfNA(x)

Impute(x, FUN = function(x) median(x, na.rm = TRUE))
```

Arguments

x the vector x, whose NAs should be overwritten with 0s.
 FUN the name of a function to be used as imputation. Can as well be a self defined function or a constant value. Default is [median](#).

Value

the edited vector x

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[replace](#)

Examples

```
z <- c(8, NA, 9, NA, 3)
```

```
ZeroIfNA(z)
# [1] 8 0 9 0 3
```

```
Impute(z)
# [1] 8 0 9 0 3
```

Zodiac

Calculate the Zodiac of a Date

Description

Calculate the sign of zodiac of a date.

Usage

```
Zodiac(x, lang = c("engl", "deu"), stringsAsFactors = TRUE)
```

Arguments

x	the date to be transformed.
lang	the language of the zodiac names, can be english (default) or german ("deu").
stringsAsFactors	logical. If set to TRUE (default) the result will consist of a factor with zodiac signs as levels.

Details

The really relevant things can sometimes hardly be found. You just discovered such a function... ;-)

Value

character vector or factor with the zodiac.

Author(s)

Andri Signorell <andri@signorell.net>, based on code from Markus Naepflin

See Also

[Year](#) and other date functions

Examples

```

         Date(1964,11,17), Date(1972,4,25)), lang="deu")
```

ZTest	<i>Z Test for Known Population Standard Deviation</i>
-------	---

Description

Compute the test of hypothesis and compute confidence interval on the mean of a population when the standard deviation of the population is known.

Usage

```
ZTest(x, ...)

## Default S3 method:
ZTest(x, y = NULL, alternative = c("two.sided", "less", "greater"),
      paired = FALSE, mu = 0, sd_pop, conf.level = 0.95, ...)

## S3 method for class 'formula'
ZTest(formula, data, subset, na.action, ...)
```

Arguments

x	numeric vector of data values. Non-finite (e.g. infinite or missing) values will be omitted.
y	an optional numeric vector of data values: as with x non-finite values will be omitted.
mu	a number specifying the hypothesized mean of the population.
sd_pop	known standard deviation of the population.
alternative	is a character string, one of "greater", "less", or "two.sided", or the initial letter of each, indicating the specification of the alternative hypothesis. For one-sample tests, alternative refers to the true median of the parent population in relation to the hypothesized value of the mean.
paired	a logical indicating whether you want a paired z-test.
conf.level	confidence level for the interval computation.
formula	a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
data	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

Most introductory statistical texts introduce inference by using the z-test and z-based confidence intervals based on knowing the population standard deviation. Most statistical packages do not include functions to do z-tests since the t-test is usually more appropriate for real world situations. This function is meant to be used during that short period of learning when the student is learning about inference using z-procedures, but has not learned the t-based procedures yet. Once the student has learned about the t-distribution the `t.test` function should be used instead of this one (but the syntax is very similar, so this function should be an appropriate introductory step to learning `t.test`).

Value

An object of class `htest` containing the results

Note

This function should be used for learning only, real data should generally use `t.test`.

Author(s)

Andri Signorell <andri@signorell.net>, based on R-Core code of [t.test](#), documentation partly from Greg Snow <greg.snow@imail.org>

with(d.oxen, ZTest(int, ext, sd_pop=1.8, paired=FALSE))
```

%like%*Like operator*

Description

The like operator is a simple wrapper for [grepl](#), whose complexity is hard to crack for R-newbies.

Usage

```
x %like% pattern
```

Arguments

x	a vector, typically of character or factor type
pattern	simple character string to be matched in the given character vector.

Details

Follows the logic of simple SQL or basic commands.

Value

a vector (numeric, character, factor), matching the mode of x

Author(s)

Andri Signorell <andri@signorell.net>

See Also

[match](#), [pmatch](#), [grep](#), [%\[\]%](#), [%overlaps%](#)

Examples

```
# find names ending on "or"
names(d.pizza) %like% "%or"

# find names starting with "d"
names(d.pizza) %like% "d%"

# ... containing er?
names(d.pizza) %like% "%er%"

# the positions on the vector
which(names(d.pizza) %like% "%er%")

# what do they look like?
names(d.pizza)[names(d.pizza) %like% "%er%"]
```

`%nin%`*Find Matching (or Non-Matching) Elements*

Description

`%nin%` is a binary operator, which returns a logical vector indicating if there is a match or not for its left operand. A true vector element indicates no match in left operand, false indicates a match.

Usage

```
x %nin% table
```

Arguments

<code>x</code>	a vector (numeric, character, factor)
<code>table</code>	a vector (numeric, character, factor), matching the mode of <code>x</code>

Value

vector of logical values with length equal to length of `x`.

Author(s)

Frank E Harrell Jr <f.harrell@vanderbilt.edu>

See Also

[match](#), [%in%](#)

Examples

```
c('a','b','c') %nin% c('a','b')
```

`%overlaps%`*Determines If And How Extensively Two Date Ranges Overlap*

Description

`%overlaps%` determines if two date ranges overlap at all and returns a logical value. `Interval` returns the number of days of the overlapping part of the two date periods. Inspired by the eponymous SQL-functions.

Usage

```
x %overlaps% y
```

```
Overlap(x, y)
```

```
Interval(x, y)
```

Arguments

<code>x</code>	range 1, vector of 2 numeric values or matrix with 2 columns, the first defining the left point the second the right point of the range.
<code>y</code>	range 2, vector of 2 numeric values or matrix with 2 columns, the first defining the left point the second the right point of the range.

Details

`%overlaps%` returns TRUE or FALSE depending on if the two ranges overlap. The function `Overlap` returns the range of the overlapping region as numeric value. This will be 0, if the ranges do not overlap.

`Interval` returns the width of the empty space between 2 ranges. Again this will be 0 if the ranges overlap.

To handle overlapping ranges there are 4 cases to consider:

```

range a:  |-----|
range b:  |-----|
range c:           |-----|
range d:           |-----|
           1  2  3  4  5  6  7  8

```

Ranges a and b overlap, the function `Overlap` will return the absolute value of the overlapping region (which will be $3 - 2 = 1$ in this case). The result will be the same for `Overlap(a, b)` and `Overlap(b, a)`.

`Interval` will have a direction. Ranges b and c do not overlap, `Overlap` will return 0, `%overlaps%` FALSE. `Interval` will return 2 for the case `Interval(a, b)` and -2 for `Interval(b, a)`.

This functions can be of value, if one has to decide, whether confidence intervals overlap or not.

Value

returns a logical vector (match or not for each element of `x`).

`Interval` and `Overlap` return a numeric vector.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

similar operators: [Between](#), [%like%](#)

for calculating the overlapping time: [difftime](#)

Examples

```

c(Date(2012,1,3), Date(2012,2,3)) %overlaps% c(Date(2012,3,1), Date(2012,3,3))
c(Date(2012,1,3), Date(2012,2,3)) %overlaps% c(Date(2012,1,15), Date(2012,1,21))

```

```

Interval(c(Date(2012,1,3), Date(2012,2,3)), c(Date(2012,3,1), Date(2012,3,3)))

```

```

# both ranges are recycled if necessary

```

```

Date(2012,1,3) %overlaps% c(Date(2012,3,1), Date(2012,3,3))

```

```
# works with numerics as well
c(1, 18) %overlaps% c(10, 45)
```

%c%*Concatenates two strings without any separator.*

Description

%c% is just a short operator implementation for `paste(x, y, separator="")`.

Usage

```
x %c% y
```

Arguments

x	first string
y	second string, which will be pasted behind the first one.

Details

R-Core does not consider it a good idea to use `+` as an operator not being commutative. So we use `c` here.

See the discussion: <https://stat.ethz.ch/pipermail/r-devel/2006-August/039013.html> and <http://stackoverflow.com/questions/1319698/why-doesnt-operate-on-characters-in-r?lq=1>

Still the paste syntax seems sometimes clumsy in daily life and so %c% might spare some keys.

Value

returns the concatenation as string.
